At Lewes Assizes Mr. Justice Avory sentenced to ix months' imprisonment in the second division eorge Tebbutt, aged 53, who was carried into court n a stretcher and laid on a table in front of the judge. Ir. Justice Avory had already resisted all appeals ıade on the ground that the man was in such a state f health that to bring him up for trial would be fatal, nd the magistrates who committed him had taken the vidence in his bedroom at his house. Tebbutt was sentenced protesting that his period of imprisonment would kill him, and there is no doubt that to laymen, at all events, his appearance was that of a man at the point of death. Nevertheless, it has been reported that when carried out of court he was able to raise himself and to bid a smiling farewell to his friends, and his case, which is certainly of an unusual character, should be of some interest to the prison medical authorities. His offence was the systematic obtaining of goods on credit without disclosing that he was an undischarged bankrupt, and the notepaper on which he wrote elaborate letters ordering the goods bore the motto "Audaces fortuna juvat"!

LIBEL ON A MEDICAL REFEREE.

At the recent assizes at Durham, before Mr. Justice Greer and a special jury, Dr. S. W. Plummer recovered £100 damages and costs in an action for libel against five officials of a miners' lodge, contained in a pamphlet circulated by them among the lodges of the Durham Miners' Association. The printers of the pamphlet were also defendants and apologised, pleading ignorance of its contents. The pamphlet was directed against Dr. Plummer in the performance of his duties as medical referee with regard, in particular, to a report made upon a young miner whose wrist had been injured in an accident. Dr. Plummer had reported inter alia that the lad had a permanent disability and "is unable to make full use of his left hand and his condition is such that he is fit for employment as a pony putter, but he could not do heavier work which involved the full use of his left hand." According to the defendants' contention pony putting was the heaviest work in the mine, and the pamphlet, after accusing the plaintiff of lack of practical experience and of making a "ridiculous" report, concluded "we respectfully ask your members to help us to turn this man off the medical referees' list." These concluding words were held by the judge to be for the jury's consideration as evidence of malice, and he therefore allowed the case to go to the jury, after having ruled that the occasion of the publishing of the pamphlet was privileged. Dr. Plummer is to be congratulated, and it seems hardly necessary to add that it is a grave hardship upon medical referees that attacks of the kind described should be made upon them by parties displeased with their reports, whether such parties be workmen or their employers.

INTERPRETATION OF SKIAGRAMS.

In an action for damages for negligence a plaintiff at Birmingham Assizes, who had been injured by a motor-van, was stated to have suffered from a fractured skull. Photographic prints were adduced as evidence in support of this when a question arose as to what these revealed. A medical man, called on behalf of the plaintiff, gave evidence that they showed a fracture of the skull. Another medical man, a radiographer, was of the opinion that no fracture was proved by the illustrations, and that the lines pointed to as indicating fracture were blood-vessels. He also spoke of the difficulty at times of drawing correct deductions from such photographs. The jury eventually awarded the plaintiff £350 damages, so presumably they preferred to rely on the evidence of more serious injury, but, of course, the views of a jury are not conclusive as to scientific evidence. The point is interesting as showing that photographs that are at all obscure should, if possible, be supplemented by fresh negatives.

RESEARCH ON PARASITES OF THE COTTON PLANT.—The Empire Cotton-growing Corporation has offered to the University of Manchester and three other institutions for a period of five years a grant to promote study of and research in mycology and entomology, with particular relation to diseases caused by animals and plant parasites of cotton. The Council of the University has accepted the offer and has appointed Mr. Samuel Wilkins, M.Sc., to supervise the department of plant diseases, and Mr. R. A. Wardle, M.Sc., to supervise investigations in entomology.

TUBERCULOSIS.

Annual Report of King Edward VII. Sanatorium, Midhurst.

On the cover of this report, which deals with the period July, 1921–July, 1922, it is stated that the charge per week has been reduced as from April 1st, 1923, to 4 guineas. This is most satisfactory and greatly to the credit of the persons concerned. Some instructive figures are published with regard to sputum tests. Of the 363 patients whose sputum was examined, 271, or 75 per cent., proved to be sputum-positive, and a comparison of the naked-eye appearance of the sputum with the microscopic findings showed that when typical, purulent sputum was examined, tubercle bacilli were demonstrable in 93·5 per cent., whereas they were found in only 17 per cent. of the watery, poor samples of sputum. Among the 271 sputum-positive cases there were 227 in which tubercle bacilli were found at the first examination, 26 on the second examination, eight on the third, and ten on subsequent examinations up to the twelfth. The interesting calculation is made that if, in a suspicious case of tuberculosis, three examinations of the sputum for tubercle bacilli yield negative results, there still remains roughly a 1–27 chance that the bacilli may be discovered on subsequent examinations during the following three months. Some of the most modern methods for treating tuberculosis in a sanatorium do not seem to be in favour at Midhurst, and the table of cases treated by artificial pneumothorax in the period under review deals with only four cases. Apparently one of the contra-indications to this treatment at Midhurst is the prospect that the patient may be unable to have "re-fills" after leaving the sanatorium.

Annual Report of Vejlefjord Sanatorium, Denmark.

The twenty-third report of Vejlefjord Sanatorium covers the period Jan. 1st–Dec. 31st, 1922, and opens with a brief obituary notice of Prof. Saugman, the creator and presiding genius of the sanatorium. Of the 145 patients discharged from the sanatorium during 1922, 129 were suitable for statistical investigations. About 56 per cent. were in the third stage, and 31·9 per cent. were confined to bed. The average duration of treatment was 208 days, and 48, or 37 per cent., of the patients were febrile on admission. Of these 48 patients, 39, or 81 per cent., became afebrile after an average interval of 50 days. Of 23 patients whose maximum rectal temperature was between 37·8° and 38° C., 21 became afebrile after an average interval of 34 days, whereas of 20 patients, whose maximum rectal temperature was between 38·1° and 39° C., 14 became afebrile after an average interval of 64 to 65 days. Some explanation for these remarkable results may be found in the section of the report dealing with the various methods of treatment adopted at Vejlefjord. Of the patients discharged in 1922, 40 were selected for pneumothorax treatment, which in 17 cases had to be abandoned on account of pleural adhesions. Fourteen underwent thoracoplasty, and one apicolysis with fat transplantation. Fifteen were treated with quartz-mercury light, and 31 with carbon arc light. X ray treatment of the spleen was undertaken in five cases, and local, Finsen-Reyn light treatment or Bacmeister's combined X ray and quartz-mercury-light treatment was given occasionally. Heliotherapy was given only in three cases, and these were, presumably, cases in which the disease was mainly surgical tuberculosis. An item of news which does not appear in this report is that Dr. Gravesen, a former assistant of Prof. Saugman's, on whom his mantle has fallen, was reading a paper on the surgical treatment of pulmonary tuberculosis on July 25th at the annual meeting of the British Medical Association.

The Grancher System of Infant Prophylaxis: Five Hypotheses Relating to Tuberculosis in Infancy.

A paper by Léon Bernard and Robert Debré in *Annales de Médecine* for May, 1923, gives an instructive account of the elaborate organisation established in Paris for isolating infants at birth from tuberculous surroundings. The expectant tuberculou mother is confined in some maternity hospital with which the central tuberculosis organisation coöperates The mother is instructed beforehand as to the fact of the situation, and her consent is obtained for th removal of her infant directly after birth. Even when only the father is tuberculous, it is usually desirable to remove the infant at once to uninfected surroundings unless the father leaves the home to enter an institution for the tuberculous. If he doe not, and the healthy mother attempts to combine wage-earning and the care of her infant, the odds are that it will suffer.

Prof. Bernard and his collaborator enunciate five hypotheses—laws, they prefer to call them—dealing with the pathology of infection with tuberculosis in infancy. The first three are fairly well established the two last are at any rate very interesting and suggestive. (1) The fate of the infant depends on its age at the time of infection. Of five infants, less than 15 days old when removed from exposure to infection, all died, whereas of 41 between the age of 6 and 18 months at the time of removal, only 10 died. (2) The next most important factor is the duration of exposure to infection. The authors compare the duration of such exposure among 33 infants who escaped contamination with the duration of exposure of 86 infants who were found to be contaminated, and the figures published show that, as a rule, the longer the exposure, the higher the rate of tuberculosis among infants. (3) Intimacy of contact also plays a part, and the authors refer to statistics published elsewhere in support of this hypothesis. (4) There is a definite relation between the gravity of the disease in infancy and the duration of the "ante-allergic" period—the incubation period or interval between the moment when exposure to infection ceases and the cuti-reaction becomes positive. The shorter this period, the more serious is the disease. (5) There are exceptions to this fifth law, but they are not common enough to invalidate it. It concerns the duration of life of the infant after exposure to infection has ceased. The authors have never observed an infant who lived for six months after exposure to infection ceased and then died of the disease. Of 36 infants dying of tuberculosis, 30 died within a month of isolation from infection by a mother or father, one died two months after isolation, one four months after, and one five months after. In other words, an infant who is still alive a month after removal from an infectious parent has excellent chances of survival.

UNITED STATES OF AMERICA.

(From an Occasional Correspondent.)

Industrial Hazards of Children.

A recent report by the Bureau of Women in Industry drew attention to the frequency of accidents to children who are employed in defiance of the law. Thus in a single year 44 children were found to have suffered injuries, involving at least a fortnight of invalidity, none of them being of the legal age in their respective employments. One boy of 11 had his hand crushed while operating an electric ice-cream freezer; another boy, only a year older, lost two fingers in feeding meat into an electric chopper. A Bill designed to prevent this illegal employment of children has been introduced into the New York State legislature. If passed it will provide double accident compensation and double death benefits for all children illegally employed.

Since July 9th a large force of New Jersey State inspectors have been investigating the conditions under which home industries are carried on. It appears that the distribution of work by New York manufacturers has been growing to very considerable proportions.

t only is the matter of child labour involved here—
d many quite young children are found to be
rking—but the sanitary conditions of these home
tories are sometimes found to be very deficient.
. Charles A. Weeks, Deputy Commissioner of
bour for New Jersey, states in an interview that his
tention has been called to several pathetic cases
ere parents living in Jersey City and Hoboken have
n working long hours in dingy, ill-lighted, and
sanitary rooms, and that in some instances children
rdly old enough to handle the work have been
essed into service. Legislation in this case is
necessary since the New Jersey State law provides
penalty of $50 for the unauthorised use of private
oms for homework of any industrial nature. The
v further provides that rooms so used shall have no
or, window, or other opening into adjoining living
oms, and that these rooms shall not be used at any
ne for living, cooking, or sleeping purposes.

Medicine in Industry.

The annual meeting of New York health officers
s held during the last week of June at Saratoga
rings. A thoughtful address on the principles of
alth supervision in industry was given by Dr.
rnard L. Wyatt, director of the Laurentide Health
rvice, Quebec. The use of the word welfare in
nnexion with industrial health service is, he holds,
eatly to be deprecated. Such service must not be a
m of philanthropy or paternalism. Nor must it be
garded as a substitute for some other essential
ctor in industrial relations. The worker expects
a steady job, (*b*) adequate real wages, (*c*) a good
eman, (*d*) a voice, individual and collective, in
tling his own conditions, (*e*) a chance to rise.
dustrial health work must supplement and not
place any of these factors. It should be undertaken
t as strike insurance, but in a spirit of service;
ose who are engaged in it must remember that the
erests both of employer and employee must be safe-
arded. The coöperation of both is needed; experi-
ce has shown, for example, that accidents cannot be
evented by rules, discipline, or appliances without
e willing and earnest coöperation of the workers
emselves. As regards financial outlay, it is more
portant to start right than to start on a large scale.
the case of one firm an extensive programme of
alth supervision was organised in the brief period
eight months, and for the next three years the
ecutives were kept busy explaining why they had
t put the money into the pay envelopes of the
rkers instead of spending it as they did. The work
ist be built upon the expanding consciousness of its
erits in the minds of those it serves. The old
nception of a "plant doctor" employed to dispense
ew pills and to dress minor injuries is giving way to
conception of industrial medicine as a preventive
her than a curative branch of the art. There are
least 700,000 accidents yearly in the United States,
which not less than 78 per cent. are preventable.
ain, the recognition of the inseparability of good
alth and efficiency may be expected to result in
velopment of the preventive side. It is clearly
ort-sighted to limit one's efforts to the eight or
e ten working hours; experience has shown the
finite advantage of some concern for the home and
mmunity conditions of the workers.

In estimating the financial return of a health
vice two principles were emphasised. In the first
ce all results are not tangible; in the second place,
ile certain maintenance charges in connexion with
alth supervision are chargeable as production and
ould be passed on to the consumer, others should be
set by savings in materials, labour turnover,
senteeism, continuity of production, and the like.
e maximum of benefits will not be attained within
ree or four years.

BURNLEY AND THE VACCINATION ACTS.—The
rnley guardians have, it is stated, decided to take no
tice of the communication of the Minister of Health
ncerning the administration of the Vaccination Acts.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Working of District Municipalities in Madras Presidency.

THE Government review on the working of the district municipalities in the Presidency for the year 1921–22, which has just been issued, contains, inter alia, the following information relating to medical affairs and public health activities:—

Medical Relief.—During the year new municipal dispensaries were opened at Vellore, Pollachi, and Calicut, and the hospital at Tirupati was converted into a dispensary. Two dispensaries at Udamalpet and Proddatur were closed. The councils maintained 54 hospitals and 44 dispensaries. The councils of Anantapur, Chingleput, Chittoor, Cuddapah, Mangalore, and Kurnool have no medical institutions, the towns being entirely dependent for medical relief on the district headquarters hospitals maintained by the Government or on private enterprise. The only municipalities which have no hospitals of any kind are Walajapet, Saidapet, Tirupati, Palakole, and Sivakasi. There were health officers throughout the year in the municipalities of Coimbatore, Calicut, Ootacamund, Tuticorin, and Trichinopoly.

Birth-rate.—The problem of improvement of the registration of vital statistics has engaged the attention of the Government for many years past. The defects of the present records were subjected to an exhaustive examination by the Director of Public Health, and the memorandum drawn up by him summarising the lines on which accuracy may be improved has since been circulated to all officers concerned. The births recorded by municipalities work out at an average of 30·3 per mille. Tiruvannamalai tops the list with a rate of 46·6.

Maternity Relief.—The councils employed 134 midwives, against 110 in 1920–21, as now reported, and the number of cases treated by them arose from 11,745 to 12,553, an average of 93 per midwife. In addition, 135 midwives were practising privately and attended 6080 cases. In all about 25 per cent. of births were attended to by qualified midwives. There are no midwives at all in Cuddapah and Salem, and in most councils this service does not receive proper attention, the staff employed being utterly inadequate. On the other hand, Mangalore has 21 trained midwives, nine of whom are employed by the municipality, who between them attended 75 per cent. of the recorded births; Trichinopoly employs six midwives, in addition to 20 other qualified midwives in the town, and the number of confinements which received skilled attention rose by about 65 per cent. For these good results the councils are indebted chiefly to the District Health and Welfare Association at work in these places.

Death-rate.—Public health was worse than in the previous year, the rate reported being 27·2 per mille, against 21·8. Gudiyattam and Bezwada head the list with 47 and 41 per mille respectively. The mortality figures for epidemic diseases are as follows: Cholera, 1861; small-pox, 1687; plague, 2151. As regards cholera, the towns with a protected water-supply did well. Apart from Cocanada, which had 117 deaths in a part of the town where piped water was not accessible, eight only showed a mortality of more than 20. There were in all 634 deaths from cholera in the 28 protected towns, and 1227 deaths in the remaining 52, the rates per mille being, protected 0·2, and unprotected 0·5. As anticipated, the small-pox epidemic assumed a severe form, being highest in Madura (466 deaths). Vaccination only slightly improved, the number of successful primary operations rising from 80,124 to 81,161, and the number per mille of the population from 32·0 to 32·4. Revaccinations increased from 26,797 to 28,360. Plague was less virulent than in 1920–21, the death-roll falling from 4914 to 2151. Influenza was responsible for 372 deaths, against 481 in the previous year.

Sanitation.—The conservancy charges rose by Rs.1·05 lakhs over that of 1920–21, the average expenditure being nearly As.9–10 per head. Private scavenging was self-supporting in 16 municipalities. The number of private latrines increased by 18,699, and the number of houses conserved by 17,685. These figures are disappointing.

Water-supply.—Twenty-eight towns in the Presidency possess a protected water-supply; in three towns new installations are under construction, and schemes have been sanctioned for four others. The present financial position makes it impossible to expect great and rapid progress in this matter.

The average consumption of water ranges from 51 gallons per head in Tirupati (no other town consumes more than 15 gallons per head per diem) to nearly 4 gallons per head in Berhampur and Guntur. Financially, the water-supply fund for all the 29 towns taken together shows a plus balance of Rs.0·80 lakh.

Drainage.—Only one town has a completed drainage system, and in two, Madura and Vellore, drainage-works are still under construction. Schemes are under discussion in no less than 25 towns, but want of funds is generally holding these up.

Government, in concluding their review, state that municipal councils evidently do not realise that in the depressed state of their finances they cannot afford to be tardy in the collection of their tax revenue or indifferent in remission or writing off of bad debts. Many irregularities have been brought to notice by the local fund auditors.

Relapsing Fever in Madras Presidency.

The Madras Presidency has until recently been, as far as is known, entirely free from relapsing fever, but towards the end of 1921 reports of cases began to be sent in to the Public Health Department, and eventually, on investigation, it was found that infection was widespread in certain districts. The first report on the subject was sent by the Director of Public Health to Government on Nov. 17th, 1922, and the Government have recently published the report along with their remarks. The Government review sums up the situation as follows: In February, 1922, the Presidency was regarded by research specialists as immune from relapsing fever, but in the following month reports were received of the occurrence of a new and deadly epidemic in the district of Tanjore. Relapsing fever had been widely prevalent in the Mysore State for some time past, and an outbreak occurred in the adjoining plateau taluk of Hosur in Salem district in October, 1921, but its scope was limited. The Tanjore outbreak, the origin of which it is impossible to trace, stands on a different footing. An elaborate investigation by the Public Health Department revealed the fact that this disease had established itself in the districts of Tanjore and Trichinopoly for seven months before it was detected by the authorities locally responsible for public health administration. The disease was restricted almost exclusively to the Paraiyar and Pallar communities; neither the local village officers, nor the landlords in whose service the Paraiyars and Pallars are employed, bestirred themselves to combat it, but the victims realised the character of the epidemic sufficiently clearly to describe it as "Paraiyars' fever," attributing it to the pollution of a sacred tank in Kumbakonam by a Paraiyar, and realising that its virulence could be abated by the simple expedient of shaving the head.

The Director's report establishes the following three points of supreme importance in public health administration:—

(*a*) Closer vigilance over vital statistics would have enabled the Public Health Department to take steps to stamp out the disease at its outset. The Director's diagrams show very clearly the existence in these villages of an abnormal prevalence of "fevers" in August and September, 1921, rising to a maximum incidence in the period December, 1921, to March, 1922. The report proves by corroborative evidence that this rise in mortality was due to relapsing fever, and that the worst was over before the disease was correctly diagnosed. The statistics also reveal the facts: (1) that adults of from 20 to 40 years of age are most susceptible to infection, while its incidence among very young and very old is comparatively light; (2) that women are somewhat more susceptible to infection than men.

(*b*) The impossibility of tracking down an epidemic of this kind unless the local health authority is equipped with a properly trained preventive staff. Only by intensive local investigation can the public health authorities locate the districts infected and take steps to eradicate the disease. The essential fact was that infection was confined to certain specified villages and to certain communities. The need for the appointment in every district of district health officers with a properly trained staff is amply justified, and when the complete scheme sanctioned comes into operation, it is inconceivable that so large an epidemic as that now under review can again run its course without detection.

(*c*) The third point is the importance of accura knowledge. The actual diagnosis of the cause of t trouble was made in the first instance by the examin tion of blood smears, at first in the Tanjore Medic School, but the work of a mobile unit of the Ki Institute staff organised to examine the disease in si met with a success impossible in the absence of su a unit. It is satisfactory that in the reorganisati of the King Institute provision has been made f field units as a permanent accessory to the Guind staff.

The Director estimates that out of 9060 attacks f which relapsing fever was accountable, no less tha 3382 ended fatally. This gives a mortality rate 37·3 per cent., but in some villages two died out every three persons attacked, while in a considerab number of villages infected from 70 to 80 per cen of the population suffered from the disease. I many households the whole family was wiped ou That the spread of infection is due to overcrowdin and dirty habits was shown by the almost complet immunity of the higher castes living in close proximit to infected hamlets.

Since the submission of this report the disease ha spread to other districts, and will probably graduall extend its ravages all over the Presidency. Preventiv measures, while simple, are by no means easy to carr out in a population of 42 millions, although it has bee possible in small areas to get considerable numbers both males and females to shave their heads. Th treatment of thousands of individuals living in remot villages in the mufussal with drugs like salvarsan i of course, out of the question. The position is ver serious.

Health Propaganda and Voluntary Associations.

The Government have just published an Orde which contains the following paragraphs:—

"The better organisation of public health propagand and the coördination throughout the Presidency of the wor of voluntary health associations have engaged the attentio of the Government for some time past. In a previous Orde a programme was laid down for the coördination of healt work through the medium of district health committee and with effect from April 1st, 1923, each district will hav a health officer. Practical experience has also been gaine of the possibilities of propaganda work in the mufussal b the deputation of four assistant surgeons early in 1922 o lecturing tours in a number of districts. The Director o Public Health's report attached as an annexure to this Orde is a most convincing testimony to the value of such work."

"On the non-official side the cause of public health ha been greatly strengthened by the reconstitution of th Health and Welfare Association and the distribution of it functions between two separate organisations: (1) th Health Propaganda Board, and (2) the Maternity and Chil Welfare Association, Madras, which is affiliated to the Lad Chelmsford All-India League. This association had, eve before the reconstruction of the Health and Welfare Association, greatly expanded its activities both in the mufussa and also in Madras City, working in the latter area in clos coöperation with the health centres of the Madras Corporation. The corporation health centres have now receive definite recognition as a Health Visitors' Training Schoo for the Presidency. A wide field has also been covere by the hookworm propaganda work of the Rockefelle Foundation."

"The Government have now before them two document which they hope will give cohesion and permanence t activities which hitherto have been somewhat discontinuous. The first is a 'Memorandum on Propaganda and Voluntary Health Work,' drawn up by the Director of Public Health, while the second document is a 'Memorandum on the Future Policy of the Health Propaganda Board.'"

The Director in his memorandum discusses the great need for propaganda work in the present state of ignorance and apathy of the people, and lays down a definite plan of campaign, at the same time outlining the official and non-official agencies already in existence. The third section of the memorandum describes the activities of the Public Health Department in connexion with the giving of popular health lectures. These lectures were given by qualified assistant surgeons and are reported to have been most successful. It is regretted that the small grant for this piece of propaganda work was cut out of the current year's budget. The fourth part of the iemorandum mentions the bodies of voluntary orkers, &c., at work in Madras city and in the iufussal, and discusses the various ways in which iese bodies may be utilised by a central propaganda rganisation. Finally, a detailed programme of work suggested, this programme including campaigns r prevention of hookworm, plague, small-pox, holera, malaria, tuberculosis, venereal diseases, for hild welfare and maternity relief work, &c. The ealth Propaganda Board is felt to be the body best iited to form the necessary link between the State nd local bodies on the one hand, and on the other the arious voluntary associations and societies. It is iggested that representatives of the various official nd non-official agencies should be elected to this oard, so that a more or less complete coördination ould be obtained. On the official side the Director f Public Health, representing the Public Health epartment, the Director of Public Instruction, epresenting the Educational Department, and the irector of the King Institute, representing the edical Department, should be coöpted members of ie Board.

The memorandum on the future policy of the ealth Propaganda Board, written by Major J. unningham, I.M.S., is also printed with the Government Order. This memorandum discusses a scheme r the organisation of public health propaganda om the non-official point of view, and while laying own certain general principles in connexion with ealth propaganda which require consideration before ie actual organisation of the central body can be iscussed, it reaches conclusions which are not at ariance with those promulgated by the Director of ublic Health. It is suggested that the Health ropaganda Board could best carry out its functions s the central organisation for health propaganda by ieans of two subcommittees which, for want of etter names, could be known as (1) the technical, and 2) the administrative. These two committees would i no sense be water-tight compartments, but would ork in the closest coördination with each other.

The Government do not discuss these two iemoranda in detail, but suggest that they deserve areful study. The Government admit the necessity r a central agency to coördinate the efforts of the umerous bodies interested in public health propaanda, but defer the question of financial assistance, s they understand the formation of such an agency under consideration. The recent visit of Sir Claude ill, the Red Cross Commissioner for the League of ations, has stimulated interest in the international ctivities of the Red Cross Society in public health ropaganda.

CONGRESS OF THE
OYAL SANITARY INSTITUTE AT HULL.

THE Thirty-fourth Congress of the Institute, which pened at the beginning of the week, bids fair to be xceptionally successful, attended as it is by over 500 elegates from this country and a large number of verseas representatives. On Sunday, July 29th, anon George Buchanan preached a striking sermon the members of the Congress, in which he developed ie theme that health and wholeness implied the same iing, and to secure real health every section of the ommunity and every phase of social life must be eached.

On July 30th the Lord Mayor of Hull received the iembers and delegates and later on opened the ealth Exhibition in the Wenlock Barracks, a building dmirably adapted for the purpose. At 5 P.M. the ight Hon. T. R. Ferens, High Steward of Hull, resident of the Congress, delivered the inaugural ldress, Dr. Louis C. Parkes, Chairman of the Council the Institute, being in the chair. Mr. Ferens made ecial reference to housing as the greatest need of the ation to-day. Hull needed approximately 6000 more ouses. It was no use, he said, attempting to instil the recept of hygiene into people who live in the many dilapidated and insanitary dwellings which to-day exist in the slum areas of all our towns and cities. As a contrast, Mr. Ferens invited the members to visit the well laid out garden village in East Hull, covering an area of 60 acres and containing 600 houses; marked improvement in health was the result of life there. Mr. Ferens also alluded to the social and hygienic work in connexion with a factory in East Hull, where over 5000 workers of both sexes are employed. Here, during the past 15 years, a whole-time doctor and a whole-time dentist have been engaged, and may be consulted at any time. Nurses are provided, and are in charge of dressing and rest rooms for casualties and slight illnesses. There are health visitors who become acquainted with home conditions of the workers. Boys and girls under 18 are taken from their work two hours weekly for drill and gymnasium at the company's cost. Dental work has proved most beneficial in the maintenance of general health; tooth-brushes and tooth-powder are bought wholesale and supplied at cost price. Applicants for employment are examined by the doctor as to their suitability for factory work. The medical examination is on very broad lines and rejections are few, consisting of those suffering from epilepsy, oral sepsis, tuberculosis, and certain heart cases.

At the conclusion of his address a vote of thanks to Mr. Ferens was proposed by Lieut.-Commander J. M. Kenworthy, M.P., and seconded by Surgeon W. W. King, of the United States Public Health Service, on behalf of the delegates from Foreign Governments. The motion was also supported by Dr. J. E. Sandilands, Executive Health Officer of Bombay, on behalf of the delegates from the Dominions, by Dr. S. J. Thacker, ex-Mayor of Christchurch, New Zealand, and by Judge W. J. Harvey, of Edinburgh, on behalf of the delegates from Municipal Authorities, and was put to the meeting by Mr. H. D. Searles-Wood, chairman of the Institute's Congress Committee.

The meetings of conferences and sections are proceeding as outlined in THE LANCET of July 21st (p. 152). Elsewhere in the present issue appears the text of Prof. F. E. Wynne's address, delivered before the Section of Maternity and Child Welfare on August 2nd. A large number of firms are displaying apparatus, materials, and preparations of interest to all concerned in hygiene and sanitation.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Lt. H. A. L. Guthrie to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Temp. Surg.-Lt. W. F. W. Betenson, late R.N., to be Surg.-Lt. (Permanent List).

Surg.-Capt. R. J. E. Hanson is placed on Retd. List at his own request.

TERRITORIAL ARMY.

Capt. A. W. Wakefield (late Canadian A.M.C.) to be Capt.

A. H. MacCulloch Eaton (late R.N.V.R.) to be Lt.

Capt. F. E. Tylecote relinquishes his commn. and is granted the rank of Maj.; and Capt. J. Macquarrie resigns his commn. and retains the rank of Capt.

Sanitary Companies: Capt. R. Cunningham (late R.A.M.C., Mila). to be Capt.

INDIAN MEDICAL SERVICE.

Col. Charles Harford Bowle-Evans, V.H.S., C.M.G., C.B.E., has been appointed Director of Medical Services in place of Lieut.-Gen. Sir C. H. Burtchaell, C.H., K.C.B., C.M.G. This is the first time that an officer of the I.M.S. has been appointed to be Director of Medical Services, and we congratulate all concerned on the departure.

The King has approved the retirement of Maj.-Gen. Sir William Rice Edwards, K.C.I.E., C.B., C.M.G., K.H.P.

THE Lancashire Asylums Board has decided to apply under a Bill now before Parliament for the name to be changed to "Lancashire Mental Hospitals Board."

ELEVENTH INTERNATIONAL PHYSIOLOGICAL CONGRESS.

THE Eleventh International Physiological Congress met in Edinburgh from July 23rd to 27th, under the presidency of Sir EDWARD SHARPEY SCHAFER. We referred in the last issue of THE LANCET to the opening of the Congress,[1] at which were present members representing over 20 nationalities. The proceedings included a graduation ceremony, at which the honorary degree of Doctor of Laws of the University of Edinburgh was conferred on the following distinguished members of the Congress: Profs. F. Bottazzi (Naples), W. Einthoven (Leiden), W. H. Howell (Baltimore), J. E. Johansson (Stockholm), A. Kossel (Heidelberg), H. H. Meyer (Vienna), Ivan Pavlov (Petrograd), and C. Richet (Paris).

At the opening session, following the official addresses of welcome on behalf of the Government, the city and University of Edinburgh, and the President's address, Prof. J. J. R. MACLEOD, of Toronto, delivered a lecture on insulin, which we published in an abridged form in our last issue.[2] A large number of other papers were devoted to various aspects of this subject. The programme was so varied and extensive that thoughout the meeting communications had to be delivered in three lecture theatres concurrently. Physiology has now become so highly specialised that many of the subjects dealt with appealed only to a small group of experts; but there were also a large number of communications which were not only of more general scientific interest, but which had a very direct bearing on the problems of clinical medicine.

Physiology of the Nervous System.

In the sections concerned with the physiology of the nervous system the question of the possible sympathetic innervation of voluntary muscles formed the subject of several papers. On the whole the tendency of the meeting was to regard the case as not proven; several workers (including Profs. Bottazzi and Hess) reported that they had been unable to find that interference with the sympathetic system had any effect on either the tone or the nutrition of skeletal muscle. One of the most interesting demonstrations was given by Prof. R. Magnus (Utrecht) on the postural reflexes due to the labyrinth and mid-brain. Prof. Magnus showed how the balancing and "righting" reactions can be analysed into a series of simple reflexes by the use of guinea-pigs and rabbits with the cerebrum removed. The clinical importance of these reflexes has been pointed out recently by Dr. F. M. R. Walshe, and their interest for the neurologist is increased by Dr. G. G. J. Rademaker's demonstration of their connexion with the red nucleus and cerebrospinal tract. In the cinematograph exhibits Prof. G. P. Zeliony (Petrograd) sent a film showing the behaviour of a dog three years after complete removal of the cerebral hemispheres. This animal illustrated certain phenomena which had not been observed by Goltz in his classical experiment, and the central nervous system in general exhibited extreme irritability. When played with the animal behaved in the manner characteristic of a puppy, lowering itself on its front legs, wagging its tail, and continuing to run and jump about.

Prof. A. KROGH (Copenhagen) gave a very beautiful cinematograph demonstration of the capillary circulation in various organs of the body. The film itself was a triumph of technique and gave a very vivid picture of the conditions under which gaseous exchange in the tissues takes place.

Physiology and Psychology.

In a most suggestive lecture entitled "Les voies non sensorielles de la connaissance et la méthode expérimentale," Prof. RICHET dealt with the borderland of physiology and psychology. He began by warning his audience that the matter which he was about to put before them was of a very revolutionary nature and was likely to meet with vigorous opposition; bu he contended that many of the most distinguished physiologists of the past had been great revolutionaries in that they had faith in the experimental method and had rejected the theories and concepts of a those who refused to take experimentation for thei guide. His thesis was to prove by the experimenta method that there were for the knowledge of reality other channels than the normal sensory channels. I was thought that we could not comprehend reality by other means than by the five senses, that a circumstance would remain still unknown to us, if sight touch, and hearing had not revealed it. That wa the classic idea. To admit, for one moment, tha consciousness could grasp a circumstance by means other than the senses, was an idea which would be regarded as revolutionary. He suggested the hypothesis that the events of the external world could actuate our intelligence in some other way which was not at present understood, by a hidden form of sensibility which he termed "cryptesthesia." He asked his audience to consider a similar example They were not conscious of any music in the room where he was speaking. They heard nothing and could almost affirm that there were no musica vibrations there. But if they took the receiver of a wireless telegraph apparatus, everybody might hear a concert which was proceeding miles away It sufficed to get a receiver to prove that there were such vibrations in their midst. Similarly there might be ways open to our consciousness other than the familiar way of the senses. In considering such possibilities, scientific investigators should not let themselves be prejudiced by the credulity of the spiritist He would like to see the facts, which depended on observation, investigated experimentally.

Physiology of the Cardiovascular System.

In the section dealing with the physiology of the cardiovascular system, Prof. C. J. WIGGERS (Cleveland) demonstrated some very beautiful instruments which he had used for making optical records of the heart sounds in man, and of the pressure changes in the heart of animals. In a series of experiments dealing with the dynamics of premature ventricular contractions in the dog produced by artificial stimulation he had found that the volume of blood discharged from the ventricles varied with the time available for ventricular filling and with the intraventricular tension, the latter factor depending not only on the duration of diastole, but also on the rate of venous filling of the heart.

Dr. J. CRIGHTON BRAMWELL and Prof. A. V. HILL (Manchester) demonstrated a very sensitive recording instrument, the "hot-wire sphygmograph," which they had used for measuring the velocity of the pulse-wave in man. From these observations they were able to determine the elasticity of the arteries in the living body, and to investigate the variations in arterial elasticity met with in different pathological conditions. This instrument had also been employed for recording muscular tremor.

Dr. JANE SANDS (Philadelphia) showed a series of X ray photographs, illustrating alterations in the size and shape of the dog's heart, following artificially induced aortic regurgitation. Immediately after operation the heart appeared longer and narrower. Later the size of the heart shadow was increased and displaced leftwards, but electrocardiographic examination did not show any evidence of left ventricular preponderance.

Nervous Activity and Heredity.

At the concluding session of the congress Prof. PAVLOV, in the course of a paper dealing with inhibition, described some extremely interesting and important experiments on conditioned reflexes. He pointed out that in this connexion a question of the greatest importance was whether the highest nervous activity—that is to say, individual perfection—might be of use to the next generation. Was it hereditary? They had tried to find the answer to that question, nd had established the conditioned food reflexes in hite mice, using the sound of an electric bell. With ıe first set of wild white mice it was necessary to epeat the combination of ringing the bell and feeding 00 times, in order to form the well-established eflexes. The next generation formed the same eflexes after 100 repetitions, the third generation fter 30, the fourth generation after 10, and the fifth fter 5 repetitions only.

---

Public Health Services.

THE HEALTH OF LONDON IN 1922.

Sir William Hamer's annual report as medical officer f health and school medical officer to the London ounty Council is so full of interesting matter that ur first obvious duty is to point out that copies can e obtained (price 2*s.* 6*d.*) from P. S. King and Sons, imited, Westminster. The death-rate of London as 13·5 in 1922, to be compared with 12·5 in 1921. he infant mortality rate was 75, and Sir William amer submits a table showing that a remarkable fall as taken place in the mortality from premature birth nd congenital defects during the past three years. is suggested that the replacement of the unqualified idwife, maternity benefit, maternity homes, and the ecent increasing concern for expectant and nursing ıothers have played their part in producing this esult. The boroughs which show the greatest relative nprovement in infant mortality since 1911–14 are reenwich, Battersea, and Poplar, while St. Pancras nd Kensington have lost place.

The small outbreaks of *small-pox* have been of a evere type, in contrast with the mild type prevalent ıtely in the North and Midlands. In all 65 cases were otified in London, of which 20 ended fatally, a case ıortality of 30·8 per cent. Of 5 cases, showing no gns of vaccination and in which vaccination was oubtful, 3 died, 2 recovered; of 14 unvaccinated 7 ied, 7 recovered; of 46 vaccinated in infancy 10 died, 6 recovered. The three shortest intervals between rimary vaccination and the attack were 14, 16, and 6 years respectively; the three shortest intervals etween primary vaccination and a fatal attack were 3, 44, and 49 years respectively. In 1901 the weak oot in the defence of London was the difficulty in lentifying many cases of the disease. Thanks to the esearch work of the late Dr. T. F. Ricketts that defect as now been remedied, and the services of Dr. . McC. Wanklyn, who has carried on the traditions f Dr. Ricketts, have been placed at the immediate isposal of the medical profession of London whenever suspected case arises.

Sir William Hamer deals again with the influence f the movement of the population on the *phthisis eath-rate* in London, and quotes Dr. M. Greenwood on ıe question of bringing "unsalted" (rural) populaons into contact with urban civilisation, and the onclusion of the latter that "adolescent migration erhaps increases mortality in both populations—rural ıortality by the withdrawal of those best fitted to ırvive under the rural environment, urban mortality y the introduction of those ill-adapted to survive nder urban conditions." The apparent arrest of the ownward trend of the phthisis death-rate in London n 1922 it was 1·08) which occurred about 1911 is ssociated with decrease in the emigration of phthisical ersons and with the transfer to London of deaths of ondon residents taking place elsewhere.

The report deals at length with the decline of *phoid fever* during the last 20 years and the disppearance of the autumnal rise, and gives an interestıg diagram showing the incidence of typhoid fever in our-weekly periods on the boroughs of London since 891. The main burden fell in the past upon people ving in certain poor areas from the thirty-seventh to ıe forty-eighth week of the year. The problem in ondon has now been narrowed down to examination of ıe parts played by fish and shell-fish respectively. After nalysis of the notification figures, Sir William Hamer concludes that there is little evidence of infection by cockles and mussels, and that "the London evidence, at any rate since 1891, incriminates mainly flat fish, generally plaice, almost always purchased as cooked (fried) fish, and often in an ungutted state." The first-hand evidence of hundreds of patients has been taken. The incriminated fish are immature plaice from 4 to 10 in. long which used to be brought to London from fishing-grounds near the mouth of the Elbe. In 1906 the London County Council raised the question with the City Corporation as to the need for the inspection of these small fish at Billingsgate, and since 1907 the fishing-grounds in question have been gradually abandoned by English trawlers. The decline of typhoid fever in London has tallied very closely with the disuse of these grounds as a source of London food-supply.

With regard to *venereal diseases*, Sir William Hamer comments with satisfaction on the decline in new cases of syphilis and the fact that the new cases of gonorrhœa are gradually approximating to the relative figures of 1 of syphilis to 3 of gonorrhœa, hitherto held to be the ratio of cases in the community. Other satisfactory features of the scheme are that the ratio of attendances to new cases goes up year by year and that the medical practitioners make increased use of the pathological facilities provided. There are 28 centres in London, and it is interesting to observe that 19·1 per cent. of the new cases attend the model clinic at St. Thomas's Hospital, and further that 28·3 per cent. of the attendances and 25·4 per cent. of the pathological examinations are made at this clinic. Sir William Hamer thinks that the failure to complete treatment is not so serious as generally supposed, and that the strictness of the definition of cure has given rise to erroneous impressions. He further states that there are good grounds for believing that the work done at the V.D. clinics in London will compare very favourably with that obtaining in those colonies where the system of compulsory notification and attendance is in operation.

The census of 1921 showed that the general distribution of the available *housing accommodation* was better than in 1911. "It is a very striking fact that in the majority of boroughs there has been a distinct improvement in respect of overcrowding conditions, especially in the central and eastern districts, which are largely occupied by the poorer classes."

Sir William Hamer gives a summary of a further investigation carried out by Dr. F. C. Shrubsall and Dr. A. C. Williams into the relationship between delinquency and *mental deficiency*. Full use is not made of the accommodation at St. Margaret's Hospital for ophthalmia neonatorum, and the Departmental Committee on Blindness think it would be preferable to secure the use of a few beds for this disease at several of the well-known teaching hospitals.

The *school report* shows that 199,812 children were inspected belonging to the three age-groups of entrants, 8-year-olds, and 12-year-olds. Of these a smaller percentage needed treatment than ever before, the percentage figure being 37·9. The figure for 1921 and 1920 was over 39, for 1919 over 42, and for 1918 44. Malnutrition was greatly reduced during the artificial prosperity of the war. In 1920 there was a set-back and remedial measures, such as school feeding and unemployment allowances, came into play, allied with children's care organisations, and now it is satisfactory to learn that the number of children actually suffering from under-nourishment is lower than when war prosperity was at its height. The wonderful progress made in cleanliness is excellent news, as also the astonishing improvement in dental conditions. Children are now leaving school who came under dental inspection at the ages 6 to 8. Unhealthy conditions of the throat and nose, though still rife, show year by year a diminishing incidence, and "there is good ground for the belief that greater attention to hygiene is really diminishing the prevalence of nasal disease." There is a diminishing number of children referred for tonsils and adenoids, and this gives an opportunity for the introduction of more adequate methods than formerly. The heavier incidence of visual defects upon girls compared with boys tends to grow less, and the medical service is consistently endeavouring to lessen the bad effects of fine work. Dr. G. Chaikin has conducted an inquiry with regard to chorea and finds a tendency for cases of chorea to follow inversely the rise and fall of the barometric pressure, but has not traced a relationship between relative humidity and the incidence of chorea. The insidious onset of rheumatism is the difficulty, and stress is laid upon the necessity for attention to unhealthy throat conditions.

Dr. C. N. Atlee has investigated the *prevalence of goitre.* Of 77 goitrous children, 21 had apparently normal health, while of the remaining 56, 10 were mentally defective, 4 were congenitally deaf, 1 had congenital heart disease, 1 congenital cataract, and 3 were epileptic. Dr. Atlee is of opinion that goitre has increased latterly. Dr. A. G. Wells reports favourable results from *ionisation for ear disease.* Of 155 children treated, 108 were put right by one ionisation.

The Board of Education have made certain suggestions for the improvement of the *treatment scheme*, and important modifications have been made in the agreements between the Council and committees of treatment centres with a view to obtaining the highest available standard of work at the centres.

SCHOOL MEDICAL SERVICE.

Blackburn.

The total number of children examined was 7487, and of these 6067 came under the code groups. Forty cases of malnutrition are recorded at routine inspection and Dr. Allen Daley refers to malnutrition as the one defect where statistics of different places are not comparable owing to the personal factor influencing the examiner's judgment as to what is malnutrition and what is not. We would refer Dr. Daley to the work of the nutrition clinics in America, where a standard ratio of heights and weights is taken for different ages, and any variation above or below this is classified. In this way a standardised conception of nutrition and malnutrition is obtained, eliminating as far as possible the personal factor.

Dr. Daley, in common with the school medical officer for Cardiff, draws attention to the large number of children not physically fit at 5 years of age, and this is true for all the country. Maternity and child welfare departments are normally responsible for safeguarding the health of children up to the age of 5 years, or previous to their admission into school. It is impossible to exercise more than a casual supervision over children more than 2 years of age, and further, mothers are usually reluctant to take older children to a clinic, which they regard as primarily for babies. It appears that the next forward step in public health administration must be concentrated on this "No Man's Land" between 2 and 5 years. School clinics are open to these children very often, but they do not by any means adequately supply the crying need of careful examination, training, and observation of these little ones, and to bridge the gap between 2 and 5 in a place like Blackburn, a nursery school is evidently called for. Forty-six children were treated for speech defects. Two revision courses of three weeks were also taken; a brief summary of the results is given:—

Speak well and clearly—no stammer ..	34
Speak with occasional hesitation	4
Improved	6
No better	2

Dr. J. Robertson investigated the alleged association between left-handedness and stammering, and it was demonstrated that there was no special connexion between them.

Carlisle.

Of the 2483 children inspected in the routine age groups, nearly 25 per cent. were referred for medical treatment, and 42 per cent. were kept under observation for defects. Of the number referred for treatment 96 per cent. received it. Malnutrition cases amounted to 379, or 15 per cent., as compared with 9 per cent. the previous year; 18 per cent. were suffering from defective vision, 2 per cent. from defective hearing; tuberculosis definite and suspected 4 per cent. The decrease in the number of cases suffering from scabies and ringworm is considerable, scabies accounting for 516 cases as compared with 2360, and ringworm 476 as compared with 3384. Dr. Joseph Beard has calculated that the eradication of scabies and ringworm has increased school efficiency since 1919 to the extent of an additional daily attendance of 77 children, or 1 per cent. on the average daily attendance. One hundred and four school-children attended the tuberculosis dispensary during the year, 15 being new and 89 old cases. The school dentist's report shows 91 per cent. of the permanent teeth examined sound, 6·2 per cent. saveable, and 1·9 per cent. unsaveable, against 88 per cent., 9 per cent., and 2·9 per cent. respectively for the previous year. He regards the production of the largest percentage possible of sound permanent teeth as the main object of school dental work. He finds that the bad septic mouth is now the exception rather than the rule, and that the children's teeth are on the whole cleaner and their mouths healthier.

Cardiff.

The total number of medical examinations for 1922 was 9911 in the routine groups and 2563 special cases. Skin disease was recorded in 7·2 per cent., defective vision in 6·6, and otitis media in 2 per cent. On the whole the proportion of children showing defects of one kind or another is remarkably constant, such slight increases as have occurred being mainly due to the increased number of special cases examined. Malnutrition was found in 0·9 per cent., these figures being the same as for 1920. Dr. Ralph M. F. Picken has set out the tables of heights and weights for 1914, 1921, and 1922, to demonstrate the absence of any notable change since the beginning of the war.

The number of children found or suspected to be suffering from tuberculosis was 76. These children were all attending school at the date of examination. During the year 17 children between 5 and 15 years of age died of tuberculosis. Remaining at the end of the year were 35 children known to be suffering from or suspected of tuberculosis and excluded from school for this reason, while other 14 children of school age had never attended because of tuberculosis. Altogether the total number of cases of tuberculosis between 5 and 15 years of age whose names remained on the records at the end of the year amounted to 123, and Dr. Picken goes on to say that none of these ought to be in attendance at the ordinary school but many would be suitable for education in a special school. Out of 4087 children commencing school life, 32·3 per cent. were found to require either medical treatment or observation. The existence of such a percentage of disease or ill-health in pre-school years definitely points to the necessity for establishing a nursery school in Cardiff to follow on the child welfare centres. Of the 2775 children requiring treatment during the year, the necessary treatment was carried out in 61·3 per cent. of the cases.

Three cases of accidentally acquired syphilis are recorded, all of which cleared up rapidly after a course of novarsenobenzol injections and hydrarg. cum cret. at the V.D. clinic. The superficial resemblance which the cases bore to ringworm, impetigo, and psoriasis diverted the attention from the possibility of secondary syphilis, and it was only after a more complete examination that the true nature of the disease was established.

Leamington Spa.

The number of children examined in the three code groups was 1102, an increase of 316 over last year. Apart from uncleanliness and dental defect, 13 per cent. were found to require medical treatment. This was carried out at the hospital in 301 cases out of the 392 requiring it. Sixty per cent. of the children in attendance at school were found to be unvaccinated, and Dr. W. L. Goldie puts this state of affairs down ore to apathy on the part of the parents than to a onscientious objection to vaccination. In the case f entrants, the figures were 2 per cent. worse than those f the previous year and 8 per cent. worse than in 1920.

Eastbourne.

The total number of children examined during the ear was 1285, 28 of these being special cases. In 48 er cent. of the cases the parents attended. Malnu-ition cases were less than half the number recorded st year owing to an improvement in economic onditions in Eastbourne. Uncleanliness and skin iseases have decreased, but no fewer than 50 per cent f the children examined had defects recorded. linics are held daily at the Town Hall, and operations re performed at the hospital. Altogether 3083 hildren attended the various clinics, making 6544 ttendances. Dr. W. G. Willoughby reports that the pen-air school opened in June, 1920, has fully justified s existence. At the end of the year there were 60 hildren, boys and girls, on the books. The majority f cases are suffering from anæmia and malnutrition, ee meals being given where necessary, also hot milk the mornings. The cost to the education authority f this school for one year was just over £28, apart om salaries.

MENTAL HOSPITALS SERVICE.

ROYAL EASTERN COUNTIES INSTITUTION FOR THE MENTALLY DEFECTIVE, COLCHESTER.

The sixty-fourth annual report of this institution an attractive publication, one of its purposes being gain new subscribers to the institution. The ustrations give a happy impression of its activities. ifluential support has been given to this institu-on throughout the Eastern Counties; a large sum added annually to the funds by means of collec-ons in various towns and districts undertaken by organisation under the direction of the Duchess Grafton. Of the children, who form the main body the inmates, a great number are cared for at rates hich bear no relation to the cost of maintenance, id the expenses of the institution, as well as its rther expansion, are therefore largely dependent on ibscriptions.

The numbers accommodated have increased greatly iring the last few years, and a sixth branch home has cently been opened. An excellent site is available r a rebuilding scheme, which would not only provide lditional and better accommodation, but simplify e management and reduce the cost of upkeep at esent involved in maintaining six separate branches attered over a wide area. The output of the work-ops, which afford occupation for many of the mates, shows a notable increase, and domestic or itdoor work of some nature, however simple, is signed to everyone capable of performing it, much the benefit even of the lower grades, who may eviously have felt that they were "no good to iyone." Games of all kinds—swimming, music, and ting and other entertainments—appear to take a rge part in the life of the institution. A small oportion of the higher-grade cases leave the institu-on to take up work elsewhere, principally domestic rvice, and this system has been successful, but its tension to factory work is at present impossible ing to the prevalence of unemployment among rmal persons.

There has been an increase in the number of ileptics admitted. The medical superintendent, . F. D. Turner, does not regard their segregation om other patients as either practicable or really cessary. The results in these cases, which at present m 13 per cent. of the total population, are disap-inting. Dr. Turner says of them: "Although we ntinue to test new remedies which are frequently ought out, I am unable to report any good results." e institution has been singularly free from infectious sease, and the deaths that have occurred have been incipally among patients of the lowest grade, in om the duration of life, owing to coincident physical bleness, rarely exceeds 25 years.

Correspondence.

"Audi alteram partem."

THE TOOTH-BRUSH AS A CARRIER OF VIRULENT DIPHTHERIA BACILLI.

To the Editor of THE LANCET.

SIR,—Mr. A. T. Pitts, in his letter to THE LANCET of June 16th (p. 1238) on "The Rôle of the Tooth-Brush," drew attention to the risks attaching to the tooth-brush as a harbourer, and therefore potential spreader, of infection. In support of his statements, and directly bearing on these risks, the following note is perhaps worthy of record.

The occurrence of several cases of diphtheria at an industrial school in the Midlands led to an investigation by one of us (G. H. C.), with the object of discovering possible factors concerned in spreading the disease amongst the boys. A certain boy (E.) had previously been found with nasal excoriation which yielded, on swabbing and cultivation, abundant *B. diphtheriæ*, and he had, in consequence, been transferred to hospital. The tooth-brush used by this boy came under suspicion as a not unlikely vehicle of infection, and, to satisfy curiosity on this point, was submitted to J. G. F. for bacteriological examination.

It should be stated that the brushes belonging to the boys were each clearly marked with the owner's number, and when not required were hung separately by means of rings from a shelf in the school lavatory. "Carbolic" tooth-powder was in general use, and was supplied to the boys from a common bowl. It was stated by the superintendent of the school that, following E.'s removal to hospital, he had as a precautionary measure soaked E.'s tooth-brush (and also the brushes of other boys) for 36 hours in a 5 per cent. solution of a disinfectant of the lysol class. During the period of about ten days, which elapsed between this soaking and its removal on May 23rd for bacteriological examination, the brush in question had been hanging in its usual place in the school lavatory.

Bacteriological Examination. — The brush was received a fortnight after being last in use by E. The lower half of the bristles and their insertion into the bone holder were coated with the remains of pink tooth-powder. About a score of bristles were detached and cultivated on the surface of plated blood-serum. After 24–48 hours' incubation it was possible to select from the mixed growth investing the various bristles a certain number of the most likely looking colonies. These were picked off and transferred to sloped serum tubes and incubated at 37° C. The sub-cultures resulting consisted of various cocci and bacilli, and included in the latter group were certain diphtheroids and what appeared to be morphological *B. diphtheriæ*. On further sub-culture the latter were definitely isolated and identified microscopically, and were also found to ferment glucose, but not saccharose. Confirmatory evidence as to the true character of the isolated organism could only be supplied by animal test. For this very necessary means of proof we are much indebted to the kindness of Drs. W. M. Scott and A. J. Eagleton, to whom separate sub-cultures were sent. Their independent results by animal-inoculation tests showed the organism to be indisputable virulent *B. diphtheriæ*.

There is, therefore, no doubt that a tooth-brush may, as Mr. Pitts stated, "harbour infection," and, although not proven in the instance here recorded, it is highly conceivable that by mixed brush contact, or if "used promiscuously" by others than its owner, the tooth-brush may lead to the dissemination of infection from an active diphtheria "carrier." The use by the boys in common of the tooth-powder bowl suggests a further possible means of spread. It would also appear that the practical disinfection of tooth-brushes, whether by the particular powder in favour or by immersion in reputed "disinfectant" solution, may be by no means as reliable or effective as is commonly believed.

Lysol Disinfection of Artificially Infected Tooth-Brushes.—To test this point under conditions as nearly approaching the real as possible, three used tooth-brushes were dipped in 5 c.cm. peptone emulsion of a 24 hours' serum slope culture of the *B. diphtheriæ* derived from E.'s brush. The brushes were then allowed to dry in the incubator in covered Petri dishes and were afterwards soaked in solutions of the same brand of lysol as that used at the school, which in 2 per cent. strength purports to kill *B. diphtheriæ* in one minute. The strengths of the lysol used for the tests were 1, 2, and 5 per cent. dilutions, in each of which the separate brushes remained for periods of 1, 5, 15, and 30 minutes, and finally 24 hours.

At the conclusion of each of the periods, and after a brief rinsing in sterile water to remove excess of lysol, bristles were extracted with every possible precaution against contamination, allowed to dry for a few minutes in sterile Petri dishes, and then transferred to the surface of plated serum for 24 hours' incubation at 37° C. Previous to the lysol immersion a few bristles were removed from each artificially infected brush for control cultivation.

The final results of a series of repeated tests were as follows: 1. *B. diphtheriæ* were isolated from each of the three controls, which were also heavily but not equally infected with various cocci, sarcinæ, and unidentified bacilli. 2. Using freshly prepared lysol solutions, *B. diphtheriæ* were successfully isolated in two series of tests from bristles of brushes which had been exposed for 1 and 5 minutes to a 2 per cent. solution, and for 1 minute to a 5 per cent. solution of lysol. A suspicious bacillus was also isolated from 5 per cent. lysol after 5 minutes' exposure, but proved to be a diphtheroid, resembling *B. xerosis*. 3. Using lysol solutions, which had been standing for at least two days, *B. diphtheriæ* were obtained from bristles after exposure to a 5 per cent. solution for as long as 15 minutes.

A culture of the *B. diphtheriæ* which had been isolated from bristles exposed to 2 per cent. lysol for 5 minutes was submitted to Dr. Scott, who again very kindly applied a guinea-pig test, and has reported the strain to be "still virulent." We are also much indebted to Dr. C. C. Okell, who found the diphtheroid, already mentioned, to be avirulent; but the *B. diphtheriæ*, surviving 5 per cent. stale lysol for 15 minutes, was virulent. Such results were to be expected, as the parent culture from E.'s tooth-brush had also proved virulent, and no change in virulence was likely to occur as the result of the surviving organism's exposure to the disinfectant.

Whilst accepting with some reserve the accuracy of the 5 per cent. strength of the lysol solution, in which E.'s tooth-brush was reported to have been soaked for 36 hours, it is not improbable that the diphtheria bacilli were in some measure protected from the action of the lysol by accumulations of oral mucus and tooth-powder adherent to the bed of the brush.

Under the conditions of the imposed tests with the various lysol solutions, no such protection was afforded to the organism on the artificially infected bristles and presumably the bacillus would be more readily killed, although it proved capable of withstanding the action of a 5 per cent. lysol solution for at least 15 minutes. Mention should be made of the omission to note a point of some importance which was overlooked in the quite unexpected discovery of *B. diphtheriæ*—namely, whether the original diphtheria colonies from E.'s brush were derived from the embedded, and therefore protected, root or from the free end of the bristles.

Subsequent attempts at some weeks' interval were made to obtain this information by planting a further series of bristles from E.'s brush on to plated serum; but the results proved inconclusive, in that the chance successful finding of *B. diphtheriæ* was not repeated; however, the embedded loops of the bristles clearly showed, from the more abundant growth, that they were more heavily contaminated than the free ends.

In view of Mr. T. H. Marshall's letter in THE LANCET also of June 16th, urging the need of "A Standard fo Lysol," it was obviously important to know th composition of the particular brand of lysol used in th above tests. For this information we are muc indebted to Mr. E. T. Shelbourn, F.I.C., whos analysis was as follows: Water, 12·5 per cent. phenolic bodies distilling between 196° and 208° C. 46·2 per cent.; soap, &c., 41·3 per cent.—i.e., ver similar to the original lysol, containing approximatel 50 per cent. cresylic acid.

The tests undertaken with lysol in the thre dilutions are not claimed to be sufficiently comprehensive as to yield a conclusive index of thi disinfectant's bactericidal power. They were applie primarily to ascertain what dilution and length o exposure were necessary to inhibit or destro *B. diphtheriæ* on artificially infected tooth-brushes Under such artificial conditions it would appear tha immersion for one minute in a 5 per cent. solution or for five minutes in a 2 per cent. freshly prepare solution of standard lysol is insufficient to kill th organism.

From the diminished bactericidal power of lyso shown by results in the third series of tests, th importance of the solutions being freshly prepare appears evident. The tooth-brushes employed differe considerably as regards their original state of bacteria pollution and their mode of construction, whic allowed of retention of impurity to a varying degree For these reasons it proved difficult to assess th strength and duration of lysol treatment required fo sterilising any individual brush. Whereas, for on less heavily infected, immersion for half an hour i 2 per cent. solution sufficed to sterilise the majority o bristles; in the case of another brush, after 24 hours in a 1 per cent. solution, the growth of cocci and spore-forming bacilli still obtained, was sufficient to mask the isolation of *B. diphtheriæ*; whilst bristles from a third brush required half an hour's exposure to a 5 per cent. solution before effectual sterilisation was reached. In the case of solutions not freshly prepared 24 hours' exposure in 2 per cent. solution was insufficient to sterilise, but 5 per cent. solution for half an hour was effective for the majority of bristles.

If, as stated, E.'s tooth-brush was soaked in 5 per cent. lysol for 36 hours, the strain of *B. diphtheria* surviving was either unusually resistant, or more probably was so protected in the deeper part of the brush as to be beyond the reach of the disinfectant. Such a brush infected by a diphtheria carrier may well require longer than half an hour in 5 per cent. solution lysol for its disinfection, and the safest course is obviously to destroy it. The fact that the tooth-brush is but one of many likely vehicles of infection from a diphtheria carrier opens up a wide field for survey—particularly in residential schools—in dealing with an outbreak of diphtheria.

Among the articles to be considered are pencils and penholders,[1] spoons and forks, common drinking cups at playground fountains, school call whistles, the mouthpieces of bugles or band instruments, and—amongst boys—the cigarette not uncommonly passed from mouth to mouth. Surgeon-Commander S. F. Dudley,[1] in drawing attention to the penholder as a possible source of spread of diphtheria infection, states: "Nearly all children bite the ends of their pens, and, as this is so, a penholder must be looked on as an even more personal article than a tooth-brush. The latter is in the mouth for shorter periods than the pen, and in addition is generally soaked with a solution of some antiseptic dentrifice."

The case here recorded, however, shows that the risk of infection attaching to the tooth-brush, despite implied antiseptic protection, may be no less than that of the penholder.

The survival of organisms on tooth-brushes exposed to lysol offers a tempting analogy to the behaviour of soil bacteria in the presence of phenol, cresylic acid, and naphthalene, suggesting that some of the varied flora the mouth may have similar powers, not only of istance to "disinfectant" action, but, as has recently n shown by experiments, with bacteria of the at Rothamsted,[2] of actual growth by splitting up antiseptic and so causing its disappearance.

ROYAL MEDICAL BENEVOLENT FUND.

To the Editor of The Lancet.

ir,—It is reported that Dr. G. E. Haslip, treasurer the British Medical Association, speaking at the ent annual meeting of the lack of support of the yal Medical Benevolent Fund, stated that "the ds are conducted in much the same way as they e 30 years ago; no new ideas are ever introduced, there is absolutely no progress."

his may be correct with respect to the administion of the Fund, probably necessarily so having ard to the limited sums at the disposal of the mmittee, but I venture to think that a new idea of rogressive nature was introduced when the medical ctitioners on the panel in Leicester consented nimously to subscribe annually towards medical allied charities a farthing for each State-insured son on their lists. This yields over £100 per annum, £50 have been given to the Royal Medical Beneent Fund for each of the last two years, and in probability a similar sum will be sent this year. remainder of the amount raised is distributed lly to medical and allied charities.

would suggest that steps be taken to urge every te insurance area in the country to follow this mple. If this were effected, the "disgrace to the fession" would be quickly removed as the sum ruing on, say, 10 million insured persons, would be vards of £10,400 per annum. This would enable the mittee to deal with a more generous hand, and the ma of "miserable doles" would be a thing of the t. I am, Sir, yours faithfully,

Astley V. Clarke,
Treasurer, Leicester Sub-Division of Union of Medical Practitioners.
icester, July 27th, 1923.

OPHTHALMOLOGICAL TRAINING FOR MEDICAL STUDENTS.

To the Editor of The Lancet.

ir,—If ophthalmology is to be made a subject for qualifying examination, in my opinion it would be isable for ophthalmologists to set out what they rd as essential for the medical student to know. clearly ophthalmology as a whole must be a postluate study. With the idea of arriving at some nite conclusion on this point, I suggested to the ncil of the Ophthalmological Section of the Royal ety of Medicine a year or two ago that I should a discussion on the teaching of ophthalmology to ical students.

o take one point, which might be usefully discussed amely, the use of the ophthalmoscope—it is quite ible for the student to learn how to handle the rument, and to see the disc, and perhaps draw t he sees. But it is impossible with the short time is disposal to acquire any useful knowledge by ns of the instrument, in the sense of being able to gnise early papillitis, slight optic atrophy, or itis. And apart from the ability to do that, I h doubt if the ophthalmoscope be of any use in ral practice.

have always grudged the relatively large propor- of time spent by students in the dark room On the one hand they were not learning anything practically useful, and on the other hand they were missing opportunities of examining cases of external diseases. conjunctivitis, iritis, and the like, cases which are of frequent occurrence in general practice, and the recognition of which is so important. And the same criticism applies, I think, to time spent in learning to estimate—as distinct from learning to recognise—errors of refraction.

I am, Sir, yours faithfully,

Harley-street, W., July 31st, 1923. Percy Flemming.

THE TREATMENT OF HABITUAL CONSTIPATION.

To the Editor of The Lancet.

Sir,—I was greatly interested in Dr. A. F. Hurst's article on the Treatment of Habitual Constipation.

I have seen some of the most serious cases of habitual constipation *cured* by the persistent use of the liquid extract of cascara, but as a rule it takes 6 to 12 months to effect a cure. At first 20 to 30 drops ought to be taken three times a day in water after meals. After a few weeks the dose can be very gradually lessened, until at the end of five or six months it is reduced to three or four drops, or even to one drop three times a day. This treatment teaches the bowels to get into the daily habit of evacuation. The difficulty is to get patients to persevere over so long a period until a cure is effected.

Habitual constipation has been treated "by suggestion." The method is certainly worth trying in some of the most serious cases. I may note a remarkable case which came under my notice. The patient, an American lady, consulted a well-known authority on hypnotism, who, after a short consultation, told her that her case was very simple, and that she would have a daily evacuation of the bowel every morning at 10 o'clock. Some time after she appeared again with the report that she was perfectly cured, but requested that the physician would make the time 9 o'clock as the earlier hour would be more convenient.

I am, Sir, yours faithfully,

Samuel R. Collier, M.D.
Wimbledon, July 24th, 1923.

THE MEDICAL DIRECTORY, 1924.

To the Editor of The Lancet.

Sir,—The annual circular has been posted to every member of the medical profession and most of the returns have already been received. If any practitioner has not yet sent us the latest information, we shall be glad to receive it by an early post.

We are, Sir, yours faithfully,

The Editors.
7, Great Marlborough-street, London, W. 1,
July 30th, 1923.

Liverpool Royal Infirmary: New Nurses' Home.—The Duke and Duchess of York paid a visit to the city on July 24th, principally for the purpose of laying the corner stone of the new building. The first portion is estimated to cost between £40,000 and £50,000, of which all but about £5000 have already been collected. The proceedings included the presentation of a Carnegie Hero Trust bronze medallion to Mr. C. R. Woods, who has been X ray operator to the infirmary since 1903, and who is now incapacitated by X ray dermatitis from further service.

People's League of Health.—The travelling scholarship prize award in connexion with the Sims Woodhead series of Constructive Educational Health Lectures recently given by the League at the headquarters of the National Union of Teachers, Mabledon-place, London, W.C., has been made to Miss Alice Gloyn. Miss Gloyn, who since 1917 has been in charge of the Camberwell Day Sanatorium, working under the London County Council in conjunction with the tuberculosis officer for Camberwell, has chosen to attend Dr. A. Rollier's course of lectures on heliotherapy at Leysin in Switzerland, from August 13th to 19th. Miss Gloyn will also visit the Grancher and other institutions in France dealing with tuberculosis in children.

he Bacteria of the Soil and the Utilisation of Organic eptics. By P. H. H. Gray, M.A. (Rothamsted). "Dis- y," June, 1923, p. 153.

Medical News.

Royal College of Physicians of London.—An ordinary Comitia of the College was held on July 26th, Sir Humphry Rolleston being in the chair.

The following candidates, having passed the required examinations, were admitted as Members :—

Drs. F. Braid, R. A. Chambers, E. F. Creed, S. W. Davidson, S. C. Dyke, H. S. Le Marquand, G. R. McRobert, O. Marriott, W. Moodie, W. J. Morrish, E. O'Flynn, A. Patrick, G. M. J. Slot, G. H. Sowry, W. B. B. Taylor, G. D. Whyte, and W. B. Wood.

Licences to practise physics were granted to 193 candidates. Diplomas were granted, jointly with the Royal College of Surgeons, in Public Health to 19 candidates, in Tropical Medicine and Hygiene to 16 candidates, in Psychological Medicine to 8 candidates, and in Ophthalmic Medicine and Surgery to 11 candidates.

The following College Officers, Members of Committees, and Examiners for the ensuing year were elected on the nomination of the President, Council, and Library Committee :—

Censors.—Dr. John Fawcett, Dr. H. Morley Fletcher, Lord Dawson of Penn, and Dr. E. Farquhar Buzzard.
Emeritus Treasurer.—Sir Dyce Duckworth.
Treasurer.—Dr. Sidney P. Phillips.
Registrar.—Dr. Joseph A. Ormerod.
Harveian Librarian.—Dr. T. H. Arnold Chaplin.
Library Committee.—Dr. Herbert Spencer, Dr. W. Cecil Bosanquet, Dr. George F. Still, Dr. Charles J. Singer.
Curators of the Museum.—Dr. J. Mitchell Bruce, Sir Seymour John Sharkey, Sir Frederick W. Andrewes, Dr. William Hunter.
Finance Committee.—Dr. Arthur T. Davies, Dr. Raymond H. P. Crawfurd, Dr. Frederick J. Poynton.
Examiners.—Chemistry : Dr. William B. Tuck and Mr. Charles S. Gibson. Physics : Dr. Frederick Womack and Dr. William E. Curtis. Practical Pharmacy : Dr. Alfred E. Russell, Dr. Edward A. Cockayne, Dr. Philip Hamill, Dr. Alfred J. Clark, Dr. Walter E. Dixon. Physiology : Dr. John B. Leathes and Dr. John Mellanby. Anatomy : Dr. Thomas B. Johnston. Medical Anatomy and Principles and Practice of Medicine : Sir Archibald E. Garrod, Dr. John H. Drysdale, Dr. Arthur P. Beddard, Dr. William C. Bosanquet, Dr. James W. Russell, Dr. Charles R. Box, Sir James Purves-Stewart, Dr. Charles Bolton, Dr. Lewis Albert Smith, Sir William H. Willcox. Midwifery and Diseases Peculiar to Women : Dr. John P. Hedley, Sir Ewen John Maclean, Dr. Thomas G. Stevens, Dr. John D. Barris, Dr. Henry J. F. Simson.
Public Health.—Part I., Dr. Henry W. Hake ; Part II., Dr. David Samuel Davies.
Tropical Medicine.—Sir Percy W. Bassett-Smith (Bacteriology) ; Sir Leonard Rogers (Diseases and Hygiene of the Tropics).
Ophthalmic Medicine and Surgery.—Dr. Gordon M. Holmes.
Psychological Medicine.—Part I., Dr. Henry Devine ; Part II., Dr. James Taylor and Dr. Charles H. Bond.
Murchison Memorial Scholarship (1924).—Dr. Robert Hutchison and Dr. E. Farquhar Buzzard.

The following communications were received :—(1) From Sir Thomas Barlow, a former president, to the Emeritus Treasurer, Sir Dyce Duckworth, offering a gift of £1000 to the general funds of the Royal College, with a view to special assistance in the probable alterations to the College buildings. The offer was accepted and a most sincere vote of thanks was voted to Sir Thomas Barlow for his generous gift.—(2) From Dr. R. W. Innes Smith offering a portrait of Sir Charles Searburgh for the acceptance of the College. The Harveian Librarian, Dr. Arnold Chaplin, pointed out that this was one of the two known portraits of this celebrated physician. The offer was gratefully accepted and the thanks of the College were accorded to Dr. Innes Smith.—(3) An invitation to the centenary of the foundation of the Edinburgh Veterinary College was received and it was left to the President to nominate a representative.

The Baly Medal was awarded, on the nomination of the Council, to Mr. J. Barcroft, F.R.S.—The President announced his award of the Bisset Hawkins Medal to Dr. T. M. Legge.—The death of the Bedell, Mr. William Fleming, was reported to the College, and in connexion therewith the following resolutions were passed :—

1. That the College desires to place on record its deep regret at the death of Mr. William Fleming, and its high appreciation of his faithful and valuable services, which extended over 50 years, during 30 years of which he held the office of Bedell to the entire satisfaction of the Fellows and of all those with whom he was brought into contact.
2. That it be referred to a committee to report on all the regulations and questions connected with the duties, residence, and remuneration of the Bedell, and of any other official who may be required to carry on the administrative work of the College.

A committee was appointed to consider and report on the question of increasing the accommodation of the College, and on the best way of doing so, should it prove desirable.—An application from Dr. Philip H. Wells for the restorati
of the membership resigned by him in January, 1922, w
granted.—A report from the representative of the College
the General Medical Council concerning the last session of t
Council, and a report from the representative of the Colle
on the Managing Committee of the Chelsea Physic Gard
were received and entered on the minutes of July 16th.—
A report from the Committee of Management, dated May 9
and July 16th, was received and adopted.—After so
formal College business, the President declared the Comit
closed.

Royal Colleges of Physicians of London a
Surgeons of England.—At a meeting of the Comitia of t
Royal College of Physicians on July 26th, and of the Coun
of the Royal College of Surgeons on July 31st, diplomas
L.R.C.P. and M.R.C.S. were conferred upon the followi
193 candidates (including 34 women) who have passed t
requisite examination of the Conjoint Board and ha
complied with the by-laws :—

Patrick M. Acheson, King's Coll. ; Noel F. Adeney, Cambri
and St. Mary's ; Katharine M. Andrew, King's Coll
William A. Atkins, Birmingham ; George F. Axon, Chari
Cross ; Shriharsh Chintaman Bakhle, Guy's ; William
Barnie-Adshead, Birmingham ; Alfred A. Battson, S
Thomas's ; Arthur Beauchamp, Birmingham ; Susanna
Bernard, Royal Free ; Douglas H. Berry, Guy's ; Jo
Bevan-Jones, Univ. Coll. ; Thomas S. Blacklidge, Guy's
Nina O. Bohtlingk, Lausanne and Charing Cross ; Edwa
R. Boland, Guy's ; William B. Boone, Oxford and London
Jogesh Chandra Bose, Baltimore and Birmingham ; John
Brew, Middlesex ; Enid A. Brock, Liverpool ; Ral
Brooke, Guy's ; Samuel N. Browne, Birmingham ; Willia
A. Caldwell, Guy's ; Ralph H. Carter, McGill and Londo
Edward H. P. Cave, King's Coll. ; Norman E. Chadwic
Cambridge and St. Bart.'s ; John H. K. Clarke and Leslie
Clarke, Birmingham ; John E. Clegg, Manchester ; Eric C.
Clouston, London ; Leon Collins, Leeds ; George G. Cook
Birmingham ; Norman B. Cooke and Victor Cotton-Cornwa
Liverpool ; Richard S. Creed, Oxford and St. Thomas's
Cecily D. Crosskey, Royal Free and Birmingham ; John
Currie and Gerald C. W. Curson, Guy's ; William Dabb
Birmingham ; Cedric K. David, Univ. Coll. ; Alfred
Davies, Birmingham ; Kenneth S. Dickinson, Durham
Michele A. Distaso, Bristol and Cardiff ; Gerrit A. Dolma
Cambridge and King's Coll. ; Helen M. Du Buisson, King
Coll. ; Geoffrey Dudley, Birmingham ; Alexander
Dyson, Oxford and St. Thomas's ; Francis Earlan
Liverpool ; Harold C. Edwards, King's Coll. ; Arthur J.

Mahoney, Madras and St. Mary's ; Leslie P. Marshal
Cambridge and London ; Charles A. Martin, London
Dorothy E. Mason, Royal Free and St. Mary's ; Hugh
Matthews, Cambridge and St. George's ; Margareth
Mautner, St. Mary's ; James Maxwell, St. Bart.'s ; Margar
S. Mills, Royal Free ; Elspeth B. Moffat, Cape and Roy
Free ; William B. R. Monteith, Cambridge and Univ. Coll.
John W. Morledge, Western Reserve ; Alfred C. Mowl
Cambridge and St. Thomas's ; John D. R. Murra
Cambridge and Middlesex ; Louis Mushin, London
Albert Nathan and Maurice Newfield, Charing Cross
Edgar Obermer, Lausanne and St. Bart.'s ; Herbert
Oldershaw, St. Bart.'s ; Carrie H. Osmond, Bristol
Chatbupuzhankaren Lonappen Ousep, Madras and Edin
burgh ; Emrys D. Owen, Cardiff ; Julian N. J. Pachec
Madras and London ; Louise O. Paterson, Royal Free
Reginald T. Payne, St. Bart.'s ; John Pearce, Westminster

Florence M. Pearson, Royal Free and St. Mary's ; Gerard G. Penman, Cambridge and St. Thomas's ; Richard P. Perera, Ceylon and London ; Alan C. T. Perkins, King's Coll. ; Leslie P. Phillips, Charing Cross ; Jeffrey W. Poole, St. Bart.'s ; Thomas H. I. Potts, Sheffield and St. Mary's ; Abraham T. W. Powell, Guy's ; Chernagiri Krishnaswami Rau, Madras and Middlesex ; Leslie Reuvid, Univ. Coll. ; Esther M. E. E. Rickard, Royal Free ; Ronald Riley, Cambridge and St. Mary's ; John Roberts, Liverpool ; Morris Robinson, Univ. Coll. ; Thomas E. Ryves, Oxford and St. Bart.'s ; Lewis H. Savin, King's Coll. ; James M. Schofield, St. Mary's ; Harry Seelenfreund, Guy's ; Wilfrid P. H. Sheldon, King's Coll. ; Ronald W. Smith and Arthur J. Smyth, Cambridge and St. George's ; Francis A. R. Stammers, Birmingham ; Doris M. Stone, Royal Free ; Robert V. Storer, Adelaide and St. Bart.'s ; George R. M. Swan, St. Thomas's ; Ronald G. Tame and Harry C. C. Taylor, Guy's ; Hugh A. Thomas, Liverpool ; Thomas B. Thomas, St. Bart.'s ; Guy L. Thompson, Cambridge and London ; John H. Thompson, Univ. Coll. ; George K. Thornton, Cambridge and St. George's ; Percy Thwaites, St. Bart.'s ; Doris Todd, Royal Free and St. Mary's ; Norman C. Tughan, Univ. Coll. ; Frank S. Vaughan, Birmingham and London ; Arnold L. Walker, Cambridge and Middlesex ; Edward G. L. Walker, St. Thomas's ; Hygeia L. J. Wallace, Royal Free and Charing Cross ; M. H. Webb-Peploe, Cambridge and St. Thomas's ; Ethel Whitby, King's Coll. ; Norman L. White, Cambridge and Univ. Coll. ; Joan F. Whitelock, Univ. Coll. ; Alan K. Wiggins, Middlesex ; Ernest G. Wilkinson, Birmingham ; Hubert C. M. Williams, St. Bart.'s ; Ronald E. Wilson, Cambridge and London ; Robert K. Wilson, London ; Ioos E. Wolf, Zurich ; Edith V. Wood, London ; Eric Wornum, Guy's ; James T. Wybourn, St. Mary's ; Harry D. Wyse, Guy's ; Mildred M. E. Yate, Royal Free ; Bhaskar Balvantrao Yodh, Bombay and London ; Joyce P. Yeoman, Royal Free and St. Mary's ; Bishai Zeitoun, Assiut and King's Coll. ; and Louis S. V. Zinober, Cape and London.

Diplomas in Tropical Medicine and Hygiene were conferred upon the following 16 candidates :—

Justin W. F. Albuquerque, Alec H. Baldwin, John Donald, Ganesh Venkatrao Gollerkeri, Arthur J. Keevill, Allan N. Kingsbury, Frank McCallum, Colin McIver, Emilio J. Pampana, Edwin Peterson, William J. E. Phillips, John L. Rebello, Anis Salama, Narinjan Singh Sethi, William H. Simmons, and Douglas J. Valentine.

Diplomas in Ophthalmic Medicine and Surgery were conferred upon the following 11 candidates :—

Monty Baranov, Thomas Butler, Richard Colley, Thomas Colley, Mahmoud A. M. El-Kattan, James G. F. Heal, Philip C. Livingstone, Brenda A. Mitchell, Zelman Schwartz, Sundar Das Sondhi, and Nand Lal Varma.

Diplomas in Public Health were conferred upon the following 19 candidates :—

Phanindra Nath Basu, William T. G. Boul, Lancelot G. Bourdillon, Frank A. J. Brodziak, Maude C. Cairney, Alan W. Carleton, Alan A. Cockayne, Katherine M. L. Gamgee, Edward Hesterlow, Neville H. Linzee, Muriel J. Lough, Donald W. McKay, Joseph L. Pawan, Sigrid L. S. Pearson, George L. Ranking, Harnath Singh, Gerald M. J. Slot, John Sullivan, and Mukund Lal Talwar.

Diplomas in Psychological Medicine were conferred upon the following 8 candidates :—

Yousif Abul-Nasr Barrada, Thomas M. Davie, Thomas L. Edwards, Mohamed Kamil El-Kholy, Frederick R. Martin, Eveleen B. G. Rivington, George W. Shore, and Peter M. Turnbull.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—E. F. Johnson, St. George's Hosp. ; W. M. Jones, St. Bart.'s Hosp. ; I. Lipman, Westminster Hosp. ; W. R. H. Pooler, Cambridge and St. Mary's Hosp. ; and A. J. Vickery, St. Mary's Hosp.

Medicine.—W. B. Arnold, St. George's Hosp. ; C. M. John, Madras and Royal Free Hosp. ; E. F. Johnson, St. George's Hosp. ; I. Lipman, Westminster Hosp. ; M. S. Mahmud (Section I.), St. Mary's Hosp. ; and S. Thompson, Leeds.

Forensic Medicine.—W. E. Farnham, Birmingham ; A. Gullertein, London Hosp. ; E. F. Johnson, St. George's Hosp. ; and H. Morris, St. Bart.'s Hosp.

Midwifery.—R. Caplan, Glasgow ; J. B. Couche, Toronto University ; W. E. Farnham, Birmingham ; E. F. Johnson, St. George's Hosp. ; J. Herbert, Guy's Hosp. ; N. Howard, Liverpool ; and R. C. Pratt, Birmingham.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery : W. E. Farnham, A. Gullertein, N. Howard, C. M. John, E. F. Johnson, and I. Lipman.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held on July 25th the following candidates, having passed the requisite examinations, were admitted Fellows :—

Tajammul Ahmed, Robert C. Begg, William E. R. Coad, Arthur Denham-White, Matthew J. Gibson, Chapple Gill-Carey, Harry M. Godfrey, Alfred W. Harley, Frank Harvey, Arthur T. Hawley, Nicholas E. Kendall, John S. Lloyd, Donald M. MacLeod, Gladys H. Marchant, Leon D. Mercer.

The following were admitted Licentiates :—

Dwijendra Nath Bhaduri and Hubert Collin van Dort.

The following candidates have passed the Final Dental Examination, and have been granted the diploma of L.D.S. R.C.S. Edin. :—

William Guild, Robert C. Cook, Jacobus M. Moll, Henry F. Skinner, Thomas T. Littlefair, William F. D. Grant, Robert W. Thackwray, James B. Cowie, Ian D. J. Smith, George M. Rose, Hector G. Robb, Alexander W. Seaton, David R. Paterson, Alexander Phillips, Walter Wyatt, Douglas M. Beaton, Thomas E. Mathias, John Ross, Francis G. Reid, and William A. Welsh.

The following passed in the subjects of pathology, medicine, and surgery :—

Stuart J. Beaton, John Dewar, George M. Brigg, Bernard S. Reynolds, Agnes M. E. Wilson, Kathleen M. Scott, Frank W. Walmsley, Alexander N. Wight, Robert Lauchlan, and Lourens W. Ackermann.

The following passed in the subjects of medicine and surgery :—

James Brydone, Lesslie Macduff, Charles E. Atkinson, and Nico H. Bartmann.

Small-pox in England and Wales. — The epidemic has apparently reached its fastigium. During the week ending July 21st only 116 new cases of small-pox (with one death) were notified in England and Wales, as against 148 (with one death) in the previous week. The distribution of these 116 cases was as follows : Derbyshire 5 (Alfreton 1, Long Eaton 4) ; Gloucestershire 65 (Gloucester 57 "including 11 cases notified as chicken-pox but rediagnosed as small-pox," East Dean R.D. 6, Gloucester R.D. 1, Stroud R.D. 1) ; Lincoln 1 (Isle of Axholme R.D.) ; Notts 17 (Nottingham 1, Kirkby-in-Ashfield 4, Mansfield Woodhouse 4, Warsop 8) ; Somerset 1 (Langport R.D.) ; Wilts 4 (Swindon) ; Yorks North Riding 2 (Middlesbrough) ; Yorks West Riding 20 (Bentley-with-Arksey 9, Doncaster R.D. 11) ; Port of Plymouth 1.

The Veterinary Profession and Public Health in Ireland.—Recently a deputation from the veterinary profession of the Free State interviewed the Minister for Agriculture and urged him to reorganise the public veterinary service of the country, with a view to safeguarding the health of the public and of live stock. The deputation suggested a thorough inspection of dairy cows, cattle marts, and abattoirs so as to prevent the transmission of communicative diseases and to secure a supply of sound animal products and the better control of contagious diseases of animals, particularly those transmissible to man. They urged strongly that there should be provision made for research into obscure diseases of animals, and drew attention to the importance, from the economic point of view, of being able to give Irish cattle a clean bill of health. The Minister, in reply, expressed his appreciation of the draft scheme submitted to him, and his willingness to do all he could to put it into effect. Our Irish correspondent adds : It is encouraging to see the veterinary and medical professions moving on parallel lines in the promotion of public health.

Metropolitan Asylums Board.—A course of instruction in the diagnosis and treatment of fevers will be held twice weekly at each of the undermentioned hospitals from October to December : Eastern Hospital, Homerton-grove, Homerton, E. 9 ; North-Eastern Hospital, St. Ann's-road, Tottenham, N. 15 ; North-Western Hospital, Lawn-road, Hampstead, N.W. 3 ; Western Hospital, Seagrave-road, Fulham, S.W. 6 ; South-Western Hospital, Landor-road, Stockwell, S.W. 9 ; Grove Hospital, Tooting-grove, Tooting Graveney, S.W. 17 ; Park Hospital, Hither Green, Lewisham, S.E. 13. A two months' course will also be held in November and December at the South-Eastern Hospital, Avonley-road, Old Kent-road, S.E. 14. Students who desire to attend a course of instruction must, before attending at the hospital, bring between 11 A.M. and 4 P.M. on any week-day (except Saturday) or send by post to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C. 4 : (1) Authority from the Dean of the Medical School. (2) Fee, £3 3*s.* for two months' course or £4 4*s.* for three months' course ; cheques to be made payable to "The Metropolitan Asylums Board." (The student must definitely ascertain before taking out his course whether he requires a two or three months' course. In the event of his taking out a three months' course, the extra £1 1*s.* will not be refunded to him, if he finds subsequently that a two months' course only is required.) (3) Full name and address and name of medical school. (4) The names of at least two of the above hospitals, arranged in the order in which the student would prefer to attend, in case the classes at any of the hospitals should be already full. A course of lectures and demonstrations in hospital administration will be given from October to December at the North-Western Hospital. Fee for the course, £3 3*s.* ; cheques should be made payable to the "Metropolitan Asylums Board." Medical men desiring to attend are required before attending at the hospital to pay the above mentioned fee to the clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C. 4, giving full name and address.

ROCKEFELLER MEDICAL FELLOWSHIPS. — The Medical Research Council announces the award of Rockefeller Medical Fellowships, tenable in the United States of America during the academic year 1923–24, to the following:—

John Crighton Bramwell, M.D. Camb., M.R.C.P., Medical Registrar and Registrar to the Cardiographic Department, Manchester Royal Infirmary.

Norman McOmish Dott, M.B., Ch.B. Edin., F.R.C.S. Edin., Assistant in the Physiological Department, University of Edinburgh.

Helen Ingleby, M.B., B.S. Lond., M.R.C.P., Assistant Physician, Victoria Hospital for Children and South London Hospital for Women.

Hugh Kingsley Ward, M.B. Sydney, D.P.H. Oxf., Member of the Scientific Staff of the Medical Research Council and working in the Department of Pathology, University of Oxford.

It is understood that further awards may be made during the coming academic year.

ASSOCIATION OF CERTIFICATED BLIND MASSEURS.—The fifth annual general meeting of this Association was held on July 19th in the Armitage Hall of the National Institute for the Blind, Great Portland-street, London, W., when Sir Robert Jones, the President of the Association, who was supported by Dr. C. Mansell Moullin, Mr. Harry Platt, and Mr. A. H. Tubby, drew the attention of the audience to the excellent report of the year's work.

IRISH HOSPITALS AND LOTTERIES.—The Committee of Dail Earann, appointed to report on the Hospital Sweepstakes Bill, reported to the Dail last week. It suggested the conditions under which it should be legal to promote lotteries on behalf of hospitals in the Free State. During the debate on the report the House was counted out. There is little prospect of the Bill going any further in the life of the present Parliament.

THE LATE DR. W. A. WALKER.—William Abraham Walker, of Southwell, Notts, who died recently at the age of 78, became M.R.C.S. in 1867, graduating M.B., C.M. Aberd. in 1868, and M.D. in 1880. At one time surgeon-major 3rd Derbyshire Regiment and a keen rider to hounds, Dr. Walker had practised little for several years; his loss will be felt by a wide circle of friends.

PUBLIC HEALTH IN SOVIET RUSSIA.—On July 21st Russia celebrated the five years' anniversary of the Commissariat of Public Health when special sessions and conferences were arranged in illustration of medical investigations and medical work in Soviet Russia. The Red Cross Society of Russia states that a special illustrated magazine will be issued under the title, "Five Years of Soviet Medicine" and pamphlets describing the work of the Commissariat in detail and the part played by Russian doctors during the five years are also to be published.

Messrs. Longmans, Green, and Co. announce that the new edition of Sir Edward Thorpe's "Dictionary of Applied Chemistry" will extend to seven volumes, of which the last volume will be largely occupied by a complete index.—Messrs. W. Heffer and Sons, Ltd. (Cambridge), announce the forthcoming publication of "The Internal Secretion of the Sex Gland," by Prof. A. Lipschütz, Professor of Physiology in the University of Dorpat, Esthonia.

LANCASHIRE COUNTY TUBERCULOSIS COMMITTEE.—The committee has offered to coöperate with the Medical Research Council by affording facilities for experiments with the Dreyer method of treatment. The Council has expressed its thanks for the offer and is considering how best to give effect to it.

MEMORIAL TO THE LATE DR. JOSHUA J. COX.—A new operating theatre in the Cottage Hospital in Buxton is to be erected by the friends and patients of the late Dr. Joshua Cox, who in 1914–17 was Principal Recruiting Medical Officer, Manchester area, and in 1917–18 Commissioner of Medical Services for the N.W. region.

THE LATE DR. F. J. KNOWLES.—The death at St. Helens on July 27th of Frederick Joseph Knowles, M.R.C.S. Eng., has removed a practitioner who was widely known outside his professional circle. Dr. Knowles was born in St. Helens, and after qualifying in 1885 at once began to practise in his native town. He was a keen Volunteer, retiring in 1910 as Lieut.-Colonel R.A.M.C., and for 30 years he was an examiner to the St. John's ambulance. He took an active interest in athletics, swimming, tennis, and cricket, and was a Freemason. His funeral, which was of a military character, was attended by almost every doctor in the district, and the streets of the town were lined by sympathetic crowds.

Parliamentary Intelligence.

HOUSE OF LORDS.

WEDNESDAY, JULY 25TH.

Therapeutic Substances Bill.

The Earl of ONSLOW in moving the second reading of the Therapeutic Substances Bill said there were certain medical preparations mainly used for the purposes of injection the strength and purity of which could be tested by analysis. The most important of these were vaccines and certain arsenical preparations and also animal extracts and insulin. The increasing use of these preparations made it necessary to establish measures for their control and regulation so that the public might be insured against danger or accident from their use, and the Bill proposed to bring these substances under control and to allow them to be manufactured in this country only under licence. The conditions of the licence were to be laid down by a Committee which would consist of the Ministers in charge of the Health Departments in this country, in Scotland, and in Northern Ireland, and they would be assisted by an advisory committee. This committee would make regulations to deal with the strength and the tests of the preparations, and they would vary the list in the schedule as scientific development dictated. The testing work would be done by the Medical Research Council so that there would be no extra expense to the Exchequer. Similar provision was made for imported substances. They would only be imported by holders of licences, and when imported they would be subject to the same tests as articles manufactured in this country. The Bill did not interfere with doctors in any way, for it did not apply to a drug prepared by a registered medical practitioner for his own patients or those of another doctor. Foreign countries for the most part had this control, or some similar form of control. The Government did not think that it ought to be possible for substances which had been rejected as not being up to the standard in the United States to be sold in this country without any penalty, as that might perhaps cause great danger to the British people.

The Bill was read a second time.

THURSDAY, JULY 26TH.

Smoke Abatement Bill.

The Earl of ONSLOW in moving the second reading of the Smoke Abatement Bill explained that it was not proposed to proceed further with the measure this session and the remaining stages would be taken in the autumn. All smoke, and not merely black smoke, was brought within the scope of the Public Health Act, 1875, and included within the term "smoke" were soot, ash, grit, and gritty particles. The fines for breaches of the law were increased, but the maximum penalty was somewhat reduced. Section 334 of the Act of 1875 was extended so as to include the processes of re-heating and annealing, hardening, forging, converting, and carbonising iron and other metals. At the end of five years any of these processes may be excluded from the section by Provisional Order. The Bill gave power to local authorities to fix their own standards for the measurement of black smoke. By Clause 3 the Minister of Health was given power to make orders extending the list of noxious or offensive gases mentioned in Section 27 of the Alkali Works Regulation Act, 1906, and the list of works mentioned in the schedule to the Act.

Viscount NOVAR, Secretary for Scotland, said he hoped to introduce a separate Bill for Scotland in the autumn.

The Bill was read a second time.

National Health Consolidation.

The Earl of ONSLOW moved the second reading of the National Health Insurance Bill, which he said was purely a consolidating Bill.

The Bill was read a second time and referred to a joint committee on consolidation Bills.

MONDAY, JULY 30TH.

Bills Advanced.

The Dentists Bill and the Therapeutic Substances Bill passed through Committee.

HOUSE OF COMMONS.

TUESDAY, JULY 24TH.

Children Employed in Mines.

Mr. DUNNICO asked the Secretary for Mines whether he was aware that boys of 14 years of age were employed in the coal-mines of this country, not only during the day but during the night also; that these boys in some areas commenced their duties between midnight and 3 o'clock in the morning; and whether he was prepared to consider the dvisability of so amending the law as to prevent the ontinuance of a system that was inimical to the physical nd mental welfare of these children.—Lieut.-Colonel LANE-ox replied: I am aware that boys of 14 may legally be mployed at night in coal-mines below ground provided that n interval of ordinarily 15 hours, and in no case less than 3 hours, separates two periods of work. I have received no epresentations that the law ought to be amended; I will ertainly give them my most careful consideration if they re made to me.

Deputy Commissioners of Medical Services.

Mr. PIELOU asked the Minister of Pensions whether he was ware that instructions had been issued to ex-Service Deputy ommissioners of Medical Services terminating their tempo-ary engagements at the end of September, and that non-ervice doctors were being retained; and whether, in view f his expressed intention of giving preference in every case o the ex-Service claims, he would arrange that preference as given to ex-Service doctors in this connexion.—Captain RAIG replied: It has been found necessary to give notice f termination of employment to 36 out of the 88 Deputy ommissioners of Medical Services employed on a six months' ontract. Of those now under notice, 30 are ex-Service and ix non-Service. There will then remain only four non-ervice Deputy Commissioners employed on a six months' ontract, and these medical officers are being retained in the terests of the pensioner in consequence of their special xperience and qualifications.

Pensioners and Tuberculosis.

Mr. MCENTEE asked the Minister of Pensions what number f men suffering from tuberculosis had applied for pensions nd had been refused a pension by his department; the umber of men so refused who had appealed against the ecision of the Ministry to the appeal tribunal; and the ercentage of such appellants who had been granted a ension.—Captain CRAIG replied: I regret that the statistics f the Ministry are not kept in a form that would enable me o answer this question in full, but I may say that during the st 15 months about 2800 claims for pension on account of uberculosis have been accepted.

WEDNESDAY, JULY 25TH.

Powers of Medical Officers of Health.

Mr. RHYS DAVIES asked the Minister of Health under hat Act of Parliament a medical officer of health had power o isolate compulsorily healthy people; and whether he ould inquire into the fact that the medical officer of health f Taunton threatened a perfectly healthy family from loucester with a period of isolation if they persisted in heir refusal to be vaccinated, and in consequence the family eturned to Gloucester, where they were examined by the mall-pox officials and given a clean bill of health.—Mr. EVILLE CHAMBERLAIN replied: I am not aware of any ct of Parliament which confers upon a medical officer of ealth power to order compulsory isolation. As regards the econd part of the question I will communicate with the ocal authority in regard to the action which the medical fficer of health is said to have taken in this case.

Health Insurance Contributions.

Major MCKENZIE WOOD asked the Minister of Health hat amounts were received in each of the years 1921 and 922 in England and Scotland, respectively, on account of ational Health Insurance contributions; and what was he shortage in each year as compared with the amounts stimated.—Mr. NEVILLE CHAMBERLAIN replied: The mounts of health insurance contributions were approxi-ately as follows: England and Wales, 1921, £22,130,000; 922, £22,500,000; Scotland, 1921, £2,740,000; 1922, 2,720,000. The shortage of contributions as compared ith the amount assumed in the financial basis of the Act—amely, about 48 contributions per insured person per annum—is estimated to be approximately 7 per cent. in England nd Wales and 10 per cent. in Scotland.

Cancer Areas.

Mr. ALFRED T. DAVIS asked the Minister of Health whether is department is collecting information with regard to what re termed the cancer areas in this country or on the Conti-ent of Europe; and what were the results, if any.—Mr. EVILLE CHAMBERLAIN replied: The subject of my hon. iend's question is receiving the attention of the committee hich is advising the Ministry on cancer problems, but there re no results which can be published at present.

Birth Control Information.

Mr. BROAD asked the Minister of Health whether his epartment would raise any objection to birth control informa-ion being given at infant welfare centres to married women ho desired it by voluntary workers attached to the centres, r otherwise to their being informed, on request, where such formation could be obtained.—Mr. NEVILLE CHAMBERLAIN plied: My view is that such information as is referred to should not be given at infant welfare centres, but that women for whom it appears to be needed on medical grounds should be referred to a private practitioner or to a hospital.

Poor-law Authorities and Small-pox.

Mr. ADAMS asked the Minister of Health whether, in view of the fact that public vaccination was controlled by the Poor-law authorities, who had no responsibility in the prevention of small-pox, he would take the necessary steps to transfer their powers in this connexion to the health authorities, who were responsible for the prevention of this disease.—Mr. NEVILLE CHAMBERLAIN replied: This suggestion is under consideration in connexion with the general question of possible amendment of the Vaccination Acts.

Use of Poor-law Hospitals.

Mr. RHYS DAVIES asked the Minister of Health whether, in view of the fact that the voluntary hospitals of the country were crowded and subject to long waiting lists and that a large number of beds were unused in the Poor-law hospitals, he could take some immediate action to remove this anomaly. —Mr. NEVILLE CHAMBERLAIN replied: I do not think I could usefully undertake any general action in the direction suggested, but I should be very glad to consider any proposals which may be put forward by boards of guardians and the authorities of the hospitals for the general use of surplus accommodation in Poor-law infirmaries.

Deaths from Starvation.

Mr. ROBERT RICHARDSON asked the Minister of Health whether he was aware that it was ascertained, by inquests, that in 1921 three persons died of starvation in the unions of Hammersmith, St. Olave, and Bermondsey, in the county of London; whether his department had taken any and, if so, what steps to prevent similar deaths; whether any and, if so, how many deaths in that county in 1922 were found by inquest to have been due to starvation or accelerated by privation; if he could supply particulars as to age, sex, date of inquest, and union concerned; whether any and, if so, what Poor-law officers were examined at the inquest; and whether any of the persons so dying in either year were tramps or homeless.—Mr. NEVILLE CHAMBERLAIN replied: I am aware that three cases of death which occurred in the County of London in 1921 were found by inquest to be due to starvation. The unions concerned were Paddington, Hammersmith, and Bermondsey. In the year 1922 no deaths in the county were found by inquest to have been due to starvation or exposure, and accordingly the third and fourth parts of the question do not arise. The death which occurred in the Hammersmith union in 1921 was that of a homeless man.

Cost of Insulin.

Viscount EDNAM asked the Minister of Health whether he was aware that diabetic sufferers were unable to obtain insulin treatment at a lower cost than 10*s.* per day, although panel patients under the Insurance Act were obtaining free treatment; and whether he would make arrangements for uninsured persons to obtain this treatment at a lower cost. —Mr. NEVILLE CHAMBERLAIN replied: I am advised that the average cost of insulin is at present about one-third of the figure stated by my noble and gallant friend, though the treatment of exceptionally severe cases such as must go to an institution may cost more. It is within the power of the guardians, on the advice of their medical officer, to pay for the supply of insulin in cases of destitution.

Viscount EDNAM: In view of the importance of this matter has not the time come for the Ministry to control the price?—Mr. CHAMBERLAIN: I do not think so, because the price has been reduced already very materially and I have good hope that it will be still further reduced.—Viscount EDNAM: It is still very high and far above the figure which an ordinary person can afford.

THURSDAY, JULY 26TH.

Ex-Service Men and Medical and Surgical Treatment.

Captain BOWYER asked the Minister of Pensions how many officers and men disabled in the great war had received medical or surgical treatment at the cost of his department. —Major TRYON replied: Approximately 1,500,000 courses of treatment have been provided by my department for the officers and men who were disabled in the great war.

Salford Public Vaccinator and the Regulations.

Mr. TILLETT asked the Minister of Health whether his attention had been called to the fact that the public vaccinator of Salford insisted on vaccinating the child of Mr. R. Headon, of 79, Nora-street, Lower Broughton, in spite of the fact that the period during which a conscientious objection to vaccination might be lodged had not expired, the child having been born on March 10th and vaccination taking place on April 19th; and what steps he proposed taking to prevent this abuse of the regulations.—Lord EUSTACE PERCY replied: My right hon. friend has communicated with the guardians in reference to this case, and I am informed that the public vaccinator called at the house of Mr. Headon on April 19th and offered to vaccinate the child; that the mother did not raise any objection or demur in any way; and that she has confirmed this statement but added that she thought vaccination was compulsory. There is no evidence that the public vaccinator insisted on vaccinating the child without the parent's consent, or of any abuse of the regulations which calls for any special action on the part of the Minister. I may add that the exemption certificate of conscientious objection is dated 25 days after the child had been vaccinated.

Cream, Milk, and Cheese Standards.

Mr. HURD asked the Minister of Health what was the present position of the movement in his department to carry out the recommendations of the departmental committee in favour of standards of quality for cream, dried milk, and cheese.—Lord E. PERCY replied: The draft regulations dealing with dried milk have now been published in accordance with the requirements of the Rules Publication Act, 1893. As regards cream and cheese I would refer my hon. friend to the answer which my right hon. friend gave on this subject on the 11th inst.

FRIDAY, JULY 27TH.

Deaths from Small-pox.

Mr. RHYS DAVIES asked the Minister of Health how many of the small-pox deaths registered during 1922 were classified as vaccinated, how many as unvaccinated, and how many as doubtful as regards vaccination; and how many of these deaths occurred in children under 5 years of age.—Mr. NEVILLE CHAMBERLAIN replied: Of the 27 deaths attributed to small-pox during 1922, 12 occurred in persons who had been vaccinated at some time in their lives. Ten among unvaccinated persons, three among those who were said to have been vaccinated but who showed no signs of vaccination, and two among those previously unvaccinated who were vaccinated during the incubation period of small-pox. There were four deaths among children under 5 years of age; of these three were unvaccinated, and one was vaccinated during the incubation period of small-pox, but had not previously been vaccinated.

MONDAY, JULY 30TH.

Medical Services for Kenya Natives.

In reply to Mr. MOREL, who asked the Under-Secretary for the Colonies whether, in view of the recent declaration of H.M. Government that the administration of the Colony of Kenya should be based upon the principle of trusteeship for the native population, he would take steps to secure that the principle be adopted that at least one-fifth of the direct taxes paid by the natives should be returned to them in technical education, medical service, and agricultural instruction.—Mr. ORMSBY-GORE replied: I should be glad if, consistently with the general financial position of the Colony, a larger proportion of revenue could be devoted to services for the direct benefit of the native. The matter will not be lost sight of, but I do not think that any fixed percentage can be laid down.

Conscientious Objection to Vaccination.

Mr. TREVELYAN THOMSON asked the Minister of Health whether, in view of the issue of Circular No. 424, dated July 23rd, to boards of guardians, a statutory declaration of conscientious objection to vaccination in the form set out in the Schedule to the Vaccination Act, 1907, would be accepted by vaccination officers in place of the new form to be issued by the Ministry.—Mr. NEVILLE CHAMBERLAIN replied: The form of statutory declaration of conscientious objection to vaccination which will be issued by my department to vaccination officers will be the form set out in the Schedule to the Vaccination Act, 1907. The Act provides that these statutory declarations must be made in that form or in a form to the like effect.

Mr. LANSBURY asked the Minister of Health whether he would explain why he had issued an order requiring a person making a statutory declaration of conscientious objection to vaccination to make such declaration only on a form supplied by the vaccination officer, in view of the provision in the Vaccination Act, 1907, Section 3, permitting the use of the form set out in the Schedule to the Act or a form to the like effect.—Mr. NEVILLE CHAMBERLAIN: The hon. Member appears to be under some misapprehension. The Vaccination Order recently issued states that these declarations must be made in a form which may be obtained from the vaccination officer or in a form to the like effect. The form issued to vaccination officers will be the form set out in the Schedule to the Vaccination Act, 1907.

Mr. EDWARDS asked the Minister of Health whether he had decided to alter the system of obtaining forms under which exemption from vaccination can be obtained and which has been in force for 15 years; and whether, in view of Section 3 of the Vaccination Act of 1907, he would state his authority for making such order.—Mr. NEVILLE CHAMBERLAIN: The answer to the first part of the question is in the affirmative. As regards the second part, the authority for the Vaccination Order recently made is contained in Section 15 of the Vaccination Act, 1871, and I find nothing in the Act of 1907 which prescribes the manner in which forms for the purpose of statutory declarations under that Act are to be obtained.

Court of Appeal for Lunatics.

Mr. ROBERT RICHARDSON asked the Minister of Health if he was aware that the recent transfer of the lunacy department by Order in Council from the Home Office to his department had had the result of throwing into abeyance many matters connected with legal sanction and the liberty of the individual; and, in view of the fact that the scope of his Ministry did not extend to judicial investigation, would he consider the possibility of instituting a court of appeal for persons unjustifiably confined in asylums.—Mr. NEVILLE CHAMBERLAIN replied: The transfer of certain powers under the Lunacy Acts to the Ministry of Health by Order in Council under the Ministry of Health Act has not had the result suggested by the hon. Member; the second part of the question does not, therefore, arise.

Nurses' Registration Rules.

Dr. CHAPPLE asked the Minister of Health whether he was aware that, under section 3 (2) (*c*) of the Nurses' Registration Act, 1919, rules were to be made enabling persons who had been bona fide engaged in practice as nurses under certain conditions to be admitted to the register, providing application was made within a period of two years after the date on which a rule first came into operation, and that a rule first came into operation on July 7th, 1923; could he now say whether persons to whom this rule applied might, if otherwise qualified, be admitted to the register; and would he say whether he had satisfied himself that the General Nursing Council was correctly interpreting the Act and the new rule.—Mr. NEVILLE CHAMBERLAIN replied: The hon. Member has not quoted the Act correctly. The wording of the section in question is "the date on which the rules to be made under the provisions of this paragraph first come into operation," and I am advised that the effect of the provision is to allow a period of two years from the date when the first body of rules came into operation. This date was the 14th July, 1921, and the two years' period having now expired the General Nursing Council have no power to admit further applications for registration as existing nurses.

Medical Women and Nurses in Fiji.

Mrs. WINTRINGHAM asked the Under-Secretary of State for the Colonies whether he could state the present numbers of men, women, and children respectively in the Indian community in Fiji; whether there were any fully trained medical women, nurses, or midwives in the islands and, if so, of what nationality; and what arrangements were made by the Fiji Government for the medical treatment of the Indians.—Mr. ORMSBY-GORE replied: The census of 1921 showed 23,407 Indians under 15 years of age, 24,886 men and 12,326 women. There were two European women medical practitioners (one of whom was presumably the Government medical officer whose agreement recently expired), and women nurses numbering 33 Europeans, 7 half-castes, 31 Fijians (not including those in the native villages), and 5 Indians. No distinction between races is made by the Government medical and hospital service, which cost in 1922 £51,319, not including buildings; that is, over 11 per cent. of the revenue.

Prison Governors as Medical Officers.

Mr. HAYES asked the Secretary of State for the Home Department the number of prison governors who were authorised to act also as medical officers; and whether he proposed to make any change in this practice.—Mr. BRIDGEMAN replied: No change in the present practice is contemplated. There is only one governor holding the necessary qualifications to act as a medical officer.

TUESDAY, JULY 31ST.

Maternity Benefit.

Mr. NEIL MACLEAN asked the Under-Secretary to the Scottish Board of Health whether it was the intention of the Scottish Board of Health to publish the Report of the Joint Committee set up in 1920, and composed of representatives from the Consultative Committee on Local Health Administration and General Health Questions and the Consultative Committee on National Health Insurance (Approved Societies' Work) to consider and report on the interrelation of maternity benefit under the Insurance Act and the maternity and child welfare schemes of local authorities; and, if so, when.—Captain ELLIOT replied: It is not proposed to publish this report.

Miners' Nystagmus.

Mr. **PALING** asked the Secretary for Mines whether any atistics were yet available showing the number of cases of iners' nystagmus at pits where electric lamps were used, as mpared with pits where oil lamps were used.—Lieut.-olonel **LANE-FOX** replied: No, Sir, as I informed the hon. ember on March 13th, such statistics would be of little lue in themselves owing to the number of factors involved.

Penrhiewtyn Hospital.

Mr. **WILLIAM JENKINS** asked the Minister of Pensions if he ntemplated vacating the hospital at Penrhiewtyn, Neath; hether he was aware that there was considerable resentment the area at the idea of its being removed; would he state e number of wounded ex-Service men now at the hospital, e number attending there for treatment, and the extent of e area it covered, and, before any step was taken, would cause full inquiries to be made and give an opportunity to presentatives of the wounded to be heard.—Captain **RAIG** replied: It is proposed to vacate the hospital emises at Neath in the autumn, when a more suitable stitution at Chepstow will be available. My right hon. iend is not aware of any objection to this change; on the ntrary he has reason to believe that the ex-Service men preciate that it is to their advantage, in view of the tter facilities for treatment which the new institution ll afford. There are at present 169 in-patients and 78 it-patients at Neath Hospital.

Deaths from Cow-pox.

Mr. **BROMFIELD** asked the Minister of Health what were the es of the seven persons registered in the year 1922 as dying om cow-pox and other effects of vaccination.—Mr. **NEVILLE HAMBERLAIN** replied: The ages were as follows: One ed 21 days; two aged 4 months; one aged 5 months; e aged 6 months; one aged 18 months, and one aged years.

Appointments.

ERRY, R. B., M.D., Ch.B. Vict., D.P.H., has been appointed Medical Officer of Health for Gloucester.

OOD, J. V., L.R.C.P., M.R.C.S., House Surgeon, Tiverton Hospital.

NES, J. W., Certifying Surgeon under the Factory and Workshop Acts for Bridgend.

ODGERS, F. M., M.D. Manch., D.P.H., Medical Superintendent of the Lancashire County Mental Hospital, Prestwich.

ENHOUSE, G. B., M.B., B.Ch. Vict., House Surgeon to Ancoats Hospital, Manchester.

NDERWOOD, J., B.Sc. Lond., M.R.C.S., L.R.C.S. Lond., M.B., B.S. Lond., D.P.H., Permanent Assistant Medical Officer, and **DALBY, MARJORIE**, M.B., B.S. Lond., D.P.H., Temporary Assistant Medical Officer for Willesden.

oyal Infirmary, Sunderland: **RUSSELL, J. N.**, M.B., Ch.B., House Surgeon; **ALLICE, MARGARET**, M.B., Ch.B. Edin., Junior Resident Medical Officer, Children's Hospital in connexion with the Royal Infirmary.

urgeons under the Factory and Workshop Acts: **ROBERTSON, D. G.**, M.B., Ch.B. Edin. (Polmont); **BIRD, J. W.**, M.R.C.S., L.R.C.P. Lond. (Egham); and **MORRIS, G. E. V.**, M.R.C.S., L.R.C.P. Lond. (Wednesbury).

Vacancies.

For further information refer to the advertisement columns.

th, Royal Mineral Water Hospital.—Res. M.O. £200.

rmingham, City Hospital, Little Bromwich.—Senior Asst. M.O. £350.

rkenhead Borough Hospital.—Hon. Skin Specialist.

rmingham, Queen's Hospital.—Third P. to Out-patients. £50.

rmingham, West Heath Sanatorium, &c.—Med. Supt. £650.

lingbroke Hospital, Wandsworth Common, S.W.—H.S. £120.

istol, Cossham Memorial Hospital, Kingswood.—H.S. £120.

mbridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæsth. £130.

rmarthenshire Education Committee.—Chief School M.O. £700.

ntral London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.

ester City and County.—Asst. M.O.H. £500.

oydon County Borough.—Deputy M.O.H. and School M.O. £780.

mberland County Council.—Asst. County M.O.H. £500.

ncaster Royal Infirmary and Dispensary.—Junior H.S. £150.

st African Medical Service.—M.O. £600.

stbourne Royal Eye Hospital.—Hon. S. and Hon. Anæsth.

eter, Royal Devon and Exeter Hospital.—H.P. £150.

minster, Devon Mental Hospital.—Third Asst. M.O. £300.

derated Malay States, Central Mental Hospital.—Asst. Med. Supt. £616.

eemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. £250.

verness, Northern Infirmary.—H.S. £120.

eds Public Dispensary.—Sen. Res. M.O. £200.

eds University, Dept. of Physics.—Prof. of Phys. Also Lecturer in Phys. £800 and £600 respectively.

Lewes Union.—M.O. for No. 1 District. £60. Also M.O. for Workhouse at Chailey. £100.

Lenham Sanatorium.—Med. Supt. £650.

Liverpool, Royal Southern Hospital.—Two H.P.'s. and Three H.S.'s. Each £100. Also Res. Cas. O. £150.

Manchester, Monsall Fever Hospital.—Jun. Med. Asst. £405 6*s.*

Manchester, St. Mary's Hospitals for Women and Children.—Asst. M.O. £100.

Mid-Wales Counties Mental Hospital, Talgarth, Breconshire.—Med. Supt. £800.

Rotherham Hospital.—Sen. H.S. £260.

Royal Naval Medical Service.—Surgeon Lieutenants.

St. Mark's Hospital for Cancer, Fistula, &c.—H.S. £200.

Staffordshire Education Committee.—Two Asst. School Med. Inspectors. £600.

West African Medical Service.—M.O. £660.

Weston-super-Mare Hospital.—H.S. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Uttoxeter, Staffs, and Crook, Durham.

Births, Marriages, and Deaths.

BIRTHS.

BESWICK.—On July 25th, at Mill Way, Mill Hill, the wife of Wilfrid Beswick, M.D., of a son.

HAMILL.—On July 24th, at St. John's Wood, N.W., the wife of Philip Hamill, M.D., D.Sc., F.R.C.P., of a daughter.

SPRIGGE.—On July 29th, at 4, Limefield-terrace, Levenshulme, Manchester, to Katriona (née Gordon-Brown), wife of Cecil Squire Sprigge—a son.

MARRIAGES.

DIBLE—ALLEN.—On July 25th, at St. Martyn's Church, Marple, Cheshire, James Henry Dible, M.B., M.R.C.P., to Marjorie Yeo, younger daughter of Mr. and Mrs. S. J. Allen, of Carlingford, Strines, Cheshire.

DEATHS.

MURRAY.—On July 28th, after an operation, Flora Murray, C.B.E., M.D., D.P.H., of Harley-street, W., and Paul End, Penn, Bucks, aged 54.

PETHYBRIDGE.—On June 27th, 1923, at 11, Whitefield-terrace, Plymouth, Walter Ley Pethybridge, B.Sc., M.D., aged 54.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, August 6th.—College closed.

TUESDAY.—10.30 A.M., Dr. Paterson: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Mr. Gibb: Eye Dept. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 3 P.M., Dr. Scott Pinchin: Medical Out-patients.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Banks-Davis: Throat, Nose and Ear Dept.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

INDEX TO "THE LANCET," VOL. I., 1923.

THE Index and Title-page to Vol. I., 1923, which was completed with the issue of June 30th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Notes, Comments, and Abstracts.

TYPHUS FEVER EPIDEMIC AMONG THE GREEK REFUGEES.

BY SIR PATRICK HEHIR, K.C.I.E., C.B., C.M.G., M.D. BRUX., F.R.C.S., F.R.C.P. EDIN.,
MAJOR-GENERAL, I.M.S. (RET.): MEDICAL ADVISER, BRITISH RED CROSS SOCIETY IN GREECE.

(Concluded from p. 210.)

Complications.

BRONCHITIS of greater or lesser severity is present in a large proportion of cases. It usually appears early, and if persistent and implicating the bronchioles, is often fatal. Bronchopneumonia is one of the commonest complications, usually affecting the bases of both lungs. Pleurisy is much less frequent, but there are few large typhus wards in which a case may not be found. In one infectious diseases hospital two of these cases were being operated on for effusion during my visit. Diarrhœa, very common in the later stages of the disease, usually begins on the eighth or ninth day, is often difficult to check, and if severe and persistent adds much to the patient's danger. Many medical men in Greece dealing with typhus on a large scale, spoke to me of implication of the heart muscles in the disease; they considered that in most cases there was a certain amount of myocarditis. I saw one case of acute endocarditis as a complication. Cardiac dilatation is likewise often present, and in the acute form is not uncommon as a terminal event in fatal cases. Parotitis is one of the more serious complications; I saw altogether 20 of these cases, as many as three in one ward of 30 patients; in two the swelling was so great and universal in the face and neck that the features were obliterated. In one hospital with 156 cases, there were only three of parotitis, and in another with 86 cases there was none. In the latter, during the early months of the epidemic, there had been altogether 12 cases. Otitis media occurs in a small percentage of cases; it may become chronic. We have seen a few of these distressing middle-ear infections among our refugees who return from the infectious diseases hospitals with a chronic suppurative discharge from one or both ears, the hearing being always defective; when both ears are involved, there is little hearing left. Actual deafness is a marked feature of many cases of typhus during the later stage of the disease; this is quite distinct from the dullness of intellect that exists at this stage. One or more cases of conjunctivitis and keratitis are often met with in typhus hospitals. Using a disinfectant eye-wash every four hours from the time of admission in one hospital stopped this form of complication altogether. Gangrene implicating the toes occasionally occurs; I saw two such cases where amputation was carried out; they recovered. Bedsores are common, especially when nursing is not of a high order.

Mortality.

There seems to be a remarkable difference in the intensity and mortality of typhus in different areas. The average mortality in the infectious diseases hospitals near Athens is roughly 10 per cent.; it is, however, much higher in some towns, such as Corfu, Patras, Volo, &c. It varies greatly at different ages, being very high (50 per cent. in some towns) in refugees of 50 years and over. The high death-rate in the old may be associated with the economic conditions of their life as refugees; I was inclined to believe that with the best nursing and care a fair proportion of these old people would recover. This belief is borne out by the experience of the Salonica Hospital. Among the 32 convalescents I saw in it on May 14th, there were one man of 65, one of 62, one of 57, two of 55, one woman of 61, one of 58, and two of 56. It seems to be largely a question of getting these old people under good nursing and treatment at an early stage of the disease. The mortality is very slight in children; their attacks are comparatively mild. I have been impressed with the higher mortality in women than in men between 20 and 50.

Prognosis.

Many circumstances affect the prognosis, but the main factors are age, sex, and the standard of efficiency in nursing in operation. Many children escape the disease altogether; those attacked usually get it in a comparatively mild, though characteristic form. Adolescents and young men (of whom we have had few) appear to struggle through the disease satisfactorily. We have had a high incidence of attacks amongst old men and women. After the age of 55 their chances of recovery are much reduced. In the Salonica Hospital, with good nursing and treatment, the typhus mortality was only 5·8 per cent., and the complications were fewer and less severe than in other infectious diseases hospitals. Complications are frequent and serious among those who are badly nursed and cared for; the mortality rises with the degree of inefficiency in nursing. In another infectious diseases hospital visited the mortality was only 7 per cent., and the complications, though serious, were less so than in most other hospitals. In two other infectious diseases hospitals the mortality was 11 and 12 per cent. respectively, and the complications formed the worst phase of the disease; in both these hospitals the nursing was defective. In none of these hospitals were there complete arrangements for protection of the sick attendants, nurses, and doctors from infection. Medical men, nurses, and all sick attendants looking after typhus patients should be thoroughly protected from lice by suitable cotton or linen clothing from head to foot before commencing their work daily, and have a bath and a complete change of clothing after finishing their day's work. Even with these precautions infections will occur during an epidemic, but without them infection is inevitable sooner or later.

Treatment.

When typhus is diagnosed the case should be sent to hospital from the refugee camp at once. To this rule we make but few exceptions; there were instances in which members of our staff were attacked and sent to isolation wards of ordinary general hospitals. It was a great concession accorded to us, and none of these cases proved fatal. The refugees were greatly opposed to our sending their infected relatives to infectious diseases hospitals, but this measure is necessary for the safety of the uninfected. Some definite routine plan must be adopted in admitting typhus fever cases into hospital and distributing them in wards. The first requirement is a receiving room to which all patients are primarily brought. Here the hair of the head is rapidly cut off with a machine clipper, the hair of the axillæ and pubes being shaved off and all hair burned. The receiving room should communicate with the room or other area containing the steam-disinfector on the one hand and with the bathroom on the other; the latter should lead to the dressing-room. After removal of the hair the patient is put on a stretcher and conveyed to the room containing the disinfector. Here everything he brings with him is discarded and disinfected. He is next taken to the bathroom and bathed, and then put on a clean stretcher and removed to the dressing-room, where he receives a suit of clean hospital clothes, being then taken to a ward. This routine must be thoroughly carried out if the wards are to be kept free from infected lice. Nothing that the patient brings to hospital should enter the ward. The carrying out of a similar routine in delousing all inmates of refugee camps is of paramount importance. All these arrangements have, of course, to be improvised in dealing with refugees. The most vitally important measure necessary at the present time is the isolation of all cases of typhus to prevent its dissemination. Thoroughly deloused typhus cases are perfectly innocuous to the uninfected, and if delousing arrangements are quite efficient there is no reason for putting them in separate wards. Personally I have seen no infectious diseases hospital in Greece that inspired complete confidence.

Typhus patients should be kept in bed throughout the pyrexial stage of the disease and for at least a week afterwards. They may be dieted on practically anything they can assimilate; the lowered digestive powers indicate the desirability of giving such foods as soups, jellies, macaroni, porridge, fish, eggs, and so forth. The more simple liquids taken—lemonade, soda and milk, weak tea, &c.—the better. Most physicians in Greece are opposed to the use of antipyretic drugs. If the temperature calls for reduction this is readily effected by cold sponging, or, if a decided effect is required, packing in cold wet sheets. There is great temptation to use aspirin or some other antipyretics; it certainly relieves the main symptoms, but it masks the patient's state and eventually depresses him considerably. In the early stage, when sleeplessness and irritability are present, small doses of morphine give satisfactory results; large doses are to be avoided as they also mask the condition and in later stages are altogether too depressing. The morphine may later on be replaced by paraldehyde or sulphonal if it is called for. The most popular stimulant is hypodermic injections of camphor (gr. 2 to 5 in 1 c.cm. of olive oil or in ether put up in ampoules) every four hours; in severe cases with threatened heart failure it is alternated with digitalin or strophanthin. Though little used in this epidemic I am convinced that the careful administration of alcohol (in the form of brandy or whisky) would tide many cases over the critical period of the disease, the ninth to the fourteenth day. It is too expensive for general use in these cases among refugees. Saline infusion subcutaneously is very commonly used and is well spoken of, as much as 1½ to 2 pints being given daily from an early stage. Some cases die of heart failure during canvalescence, owing t is said, to overstrain of the myocardium, which is seriously nvolved. This involvement of the heart muscle demands are in convalescence ; the only treatment required appears o be a tonic of strychnine, strophanthin or digitalis, and iron, asily assimilable nourishing food, and gentle exercise. Normally cases are kept in hospital 14 to 21 days from the irst day of apyrexia. With great pressure on hospital ccommodation the cases are sometimes discharged at the nd of the first week ; as they are then (if they again become ousy) for some days infectious to those around them, heir freedom from lice must be assured. Eye affections, specially conjunctivitis and keratitis, may to a large extent e prevented by the use of suitable collyria from the beginning ; parotitis, otitis media, and possibly pulmonary omplications may be reduced by the use of gargles, mouthwashes, and swabbing the throat with appropriate antiseptics.

The treatment for typhus adopted in the infectious liseases hospital at Salonica is as follows. *Diet.*—Milk 14 ounces (1 oke) daily, meat soup twice a day, egg-flip wice, lait caillée (yaourt) once a day, sour milk and emonade ad lib. This is the adult diet, modified as required. *Drugs.*—The following are most generally employed : Camphor (gr. 2 to 5) in olive oil (made up in ampoules) every our hours or so subcutaneously after the first week ; adrenalin ne ampoule daily ; spartein and strychnine on alternate lays ; caffein once a day. When necessary, either sulphonal or paraldehyde is used to induce sleep. Occasionally luring the first week small doses of morphine are given to alm the patient. Purgatives are not given ; constipation s the rule, and it is relieved by simple enemata. I was urprised to find so little serious diarrhœa and rectal incontinence in the later stages of serious cases as compared with hose in other hospitals, even our own. For headache and oisy delirium ice is applied to the head ; for high temperature old sponging, and where hyperpyrexia threatens cold heet packing is employed. The eyes are washed with oric acid lotion, the mouth with an antiseptic, and the throat wabbed every four hours ; a gargle and mouth-wash are iven if the patient can use them. Since this latter routine as been adopted complications have greatly decreased. aline solution is infused into the subcutaneous tissues twice day or so, 12 ounces at a time. Serum treatment is not dopted. A trial was made of defibrinated typhus blood ncubated for three days at 37° C. with ox-gall, and then eated to 60° C. for two hours. The dose given was 2 c.cm. nce a day. It was used in 50 cases with no obvious good ffects and then abandoned. Massage is looked upon as a aluable accessory to the treatment and is carried out in very case twice a day.

Very little is done in this epidemic in connexion with pecific treatment by the use of sera of typhus convalescents.

Prophylactic Inoculations.

A lasting immunity to typhus is established by a previous ttack. In Asia Minor and the Levant generally typhus is lmost endemic, and it is probable that many of those refugees ho have escaped in the present epidemic have acquired mmunity by a previous attack in childhood. It is possible, lso, that an immunity of limited duration may be acquired y the inoculation of the virus of the disease obtained from yphus cases in the early stage of the disease. As a substitute for a prophylactic vaccine the blood of typhus fever ases has been inoculated and the virus thus introduced in living state. The killed virus is used here.

Inoculation against typhus is being adopted in Greece ; is at present experimental, and, of course, voluntary. was inoculated a few days after my arrival in Greece and ow all employed on British Red Cross work have been done. here is absolutely no reaction. Dr. Georges Blanc, irector of the Institut Pasteur Hellénique, who is on pecial duty in connexion with this work, tells me that he has ot heard of any inoculated person acquiring the disease, ut expresses no opinion regarding its prophylactic effects present. I understand that if favourable reports regarding s value are forthcoming in due course, the Greek Government propose making inoculation compulsory among fugees occupying infected areas.

Prevention.

The carrying out of preventive measures in a refugee camp comparable with nothing met with in ordinary civil or ilitary life in the United Kingdom ; the closest approach to I know of is work among famine-stricken areas in India. far as the area allotted to the British Red Cross is concerned, the typhus epidemic is now well under control, and is anticipated that the disease will die out within the next ur or five weeks. It is beyond the power of human effort mpletely to eradicate it under existing circumstances. our jurisdiction we have had only three cases during the st 19 days. I confess that initially I had hoped for more dical results, but I had not then had my later disappointing perience in all work where Greek refugees form part of the ganisation. With regard to our particular charge in and ar Athens I recently wrote to the British Red Cross in London that throughout March much energy was concentrated in endeavouring to reduce, if not eradicate, the typhus epidemic among our refugees. It was recognised that while the typhus outbreak lasted there must be a great deal of apprehension among the refugees themselves and a certain amount of risk to the staff in their daily work. A sight deserving of permanent record is that of the British nursing sisters examining the heads and clothes of the refugees for lice and nits, and coercing the hosts of these insects against their will to be de-verminised in the bathrooms. All men's and boys' heads were shaved, and all girls up to the age of 14 had their hair bobbed. All cases of actual typhus, of course, had their heads shaved. These were severe measures and led to some mutinous display among the refugees, but this exhausted itself when it was recognised that these were compulsory measures adopted for their personal safety. Our nursing sisters also used on the heads of the refugees in camp the mixture of equal parts of kerosene and olive oil we employ to free nits from hair, and they distributed N.C.I. powder (naphthalene 96 parts, creosote 2 parts, iodoform 2 parts), which was in little bags to be worn continuously for a week, when a fresh bag is issued. The idea is that the heat of the body helps to vapourise the ingredients and creates a louse-destroying atmosphere next the skin and clothes.

I believe it to be well worth while in every camp to endeavour to educate the people in regard to the nature of typhus and the principles that underlie its eradication and prevention. We placarded leaflets in this connexion and also had them read out periodically for the benefit of the illiterate. We also posted up such short notices as : "Lice cause typhus fever" ; "It is disgraceful to have lice in the head," and so on.

The specific measures now indicated appear to be—(1) dispersion of refugees from overcrowded towns to rural areas as much as possible ; (2) an increased supply in many towns of water which should be available to, or at least be within easy reach of, every house. In some camps the water-supply is decidedly defective, and bathing arrangements, steam-disinfection of clothing and bedding, and ordinary laundry-work are seriously interfered with. The Greek administration is endeavouring in all possible ways to remove this difficulty.

Every effort to quarantine contacts has failed, which, all things considered, was to be expected. All we want is that the contact should be definitely watched for 21 days, the time laid down as the maximum incubation period. We endeavoured, as far as was possible, to render these certificated people free from lice ; we felt that if thus free they could not communicate typhus, even if they acquired it themselves in the meantime. The quarantining of contacts in a small country which contains over a million and a quarter of refugees, many thousands of whom are contacts and are either in search of work or have daily to pass in and out of the camps to and from their work, is an impossibility. We hope that during the summer the epidemic will come naturally to an end by cessation of the multiplication of lice in unfavourable meteorological conditions, and that by the beginning of the next typhus season the economic and other conditions at present antagonistic to preventive work will have altered for the better.

PREVENTION OF DECAY OF TEETH.

A LEAFLET for the use of parents, dealing with the causes of decay in teeth and its prevention, has just been issued with the approval of the Council of the Society of Medical Officers of Health. The leaflet reads as follows :—

Decay of teeth is caused by the fermentation of food that sticks on or between the teeth after meals. Acid is formed from the food, and this acid eats a hole into the teeth. It is only the "starchy" and "sugary" foods (see below) that form acid in the mouth.

It is most important that the jaws should be well grown and the teeth regular. This is brought about by breathing through the nose from birth onwards and by chewing and gnawing. If the jaws are small and the teeth overcrowded, mastication (chewing) cannot be properly performed, and the food will be left clinging to the teeth after meals and the teeth will decay.

Seven Rules.

In order that the jaws and teeth shall grow properly and the teeth kept clean and free from decay, you should observe the following rules :—

(1) As soon as an infant needs food other than milk (8 to 9 months) give it in a solid form, such as crusty bread, twice baked bread, or crisp toast, thus compelling mastication. Do not give bread soaked in milk or milk thickened with flour or other starchy foods, such as most patent foods. Encourage the child to chew and see that it breathes through its nose. In these ways good habits of mastication will be formed.

(2) As the child grows up you should still give most of the food in a solid form, compelling mastication. Food, other than milk, should rarely be taken in a liquid form. Vegetables and meat should not be minced and soaked in gravy. Bread should not be eaten new, and it should have plenty of good firm crust.

(3) After the first two or three years of life the child should have three meals a day and no food between.

(4) It is not advisable to drink at meal times, but plenty of water should be taken between meals. Milk is a food, and should only be taken at meal times, and must be followed by a tooth-cleansing food.

(5) All meals should be finished with a cleansing food (see below).

(6) Sweets, chocolates, and biscuits are very harmful to the teeth, if taken the last thing at night. They should only be taken at meal times, and should be followed by a cleansing food. The custom of giving milk and biscuits the last thing at night should not be allowed.

(7) Correct feeding and chewing are the best means of preventing decay of the teeth, though the intelligent use of the toothbrush will be found helpful.

If decay of the teeth or tenderness of the gums is noticed, the child should be taken to a dentist. Such conditions prevent mastication and bring about further decay. It is important for the sake of the child that the nursing and expectant mother should also go to the dentist if her teeth are in a bad condition.

Examples of the Various Kinds of Food.

Starchy Foods.—Potatoes; rice, tapioca, sago; bread, biscuits, &c.; oatmeal porridge; most patent foods.

Sugary Foods.—All foods to which sugar is added; sweets of all kinds; honey, syrup, jams, marmalade; milk.

Tooth Cleansing Foods.—Fresh fruits: apples, oranges, nuts; raw vegetables: lettuce, watercress, celery, radishes, onions; crusts[1] of bread, crisp toast, twice-baked bread; meat, fish, bacon.

The leaflet may be obtained from John Bale, Sons and Danielsson, Ltd., 83–91, Great Titchfield-street, London, W. 1., price 1*d.* each, 3*s.* 9*d.* for 100.

TEREBENE TOILET SOAP.

TEREBENE (Terebenum) is a well-known powerful antiseptic, disinfectant and deodorising liquid and its distinctive smell makes it particularly suitable for combination with toilet soap. The glycerine soap supplied by Messrs. F. S. Cleaver and Sons, Ltd., Honey Soap Works, Twickenham, Middlesex, a sample of which has reached us, has behind it a reputation of 50 years, and its soothing and antiseptic qualities recommend it as excellent for the toilet. Attention has already been drawn in these columns to the value of "Talcum," also supplied by this firm, as a pure talc powder for use in the nursery and wherever a dusting powder of this kind is indicated.

QUEEN MARY'S CONVALESCENT AUXILIARY HOSPITALS, ROEHAMPTON.

A STATEMENT has been issued by the committee of the hospitals dealing with the work accomplished therein from 1915 to 1923, and with plans for the future. Approximately 41,000 men required artificial legs and arms as a result of the war; the majority of these cases were dealt with at Roehampton House, opened on June 28th, 1915, with 25 beds, and later increased to 224 beds in October, 1915, to 550 beds in June, 1916, and to 900 beds in June, 1918. Since June, 1915, nearly 23,000 new patients passed through the hospitals, and over 47,000 cases were readmitted for second limbs and repairs. In addition, since January, 1918, nearly 20,000 cases were dealt with through the post. In 1916 instructional workshops and an employment bureau were opened in connexion with the institution; 8453 men received training in various trades and commercial classes, employment was found by the bureau for 4987 men on discharge from hospital, and for 4166 men arrangements were made for training in various trades after discharge from hospital. The instructional workshops are now closed as, happily, most of these disabled men have found suitable employment.

Now that practically all officers and other ranks have received their duplicate limbs the number of in-patient beds is 250. The out-patient department has, however, increased very considerably; the average attendance is about 52 per day, rising in busy seasons to as many as 90. Dover House (adjoining Roehampton House), for the use of officers, is now closed, and arrangements have been made for their accommodation at Roehampton House, where 13 beds are available. In consequence of the number of surplus beds, arrangements are being made with the Ministry of Pensions for the accommodation of 500–600 general medical and surgical cases from the Special Surgical Hospital, Shepherd's Bush, which is closing at the end of the year. This will necessitate a further large capital expenditure for the alteration of existing huts and the erection of new semi-permanent wards, operating theatres, &c. The care of the limbless patients is in no way to be interfered with by this arrangement, and it is hoped to further extend the benefits of Roehampton to a limited number of railway employees and others who have the misfortune to lose their limbs in the course of their employment.

It is hoped that support by donations and endowment of beds may continue, so that the committee may be able, with the help of the capitation grant received from the Government, to maintain the institution in its present high state of efficiency. The hon. treasurer of the hospital is Sir Charles H. Kenderdine, K.B.E., 12, Little College-street, London, S.W. 1.

PUBLIC HEALTH IN SOUTH AFRICA.

THE Official Year Book of the Union of South Africa[1] contains a chapter devoted to public health and hospitals in the Union. The history of public health prior to the Union and from 1910 onwards is briefly traced, and particulars are given as to the appearance and prevalence of certain diseases, among which are the following: Cholera has twice appeared since 1888 in ships bound from Asiatic ports, but no epidemic has occurred on land. Diphtheria occurs throughout the Union, especially during the colder months, but serious outbreaks are rare. Bacterial dysentery of a mild type is not uncommon in summer, but amœbic dysentery is comparatively rare. The annual notifications of typhoid or enteric number between 4000 and 5000. South Africa suffered heavily during the influenza epidemic of 1918, there being 139,471 deaths up to the end of November of that year. Leprosy, which existed among the Hottentots before the arrival of Europeans at the Cape, had been separately dealt with by several of the component States before the Union came into being; the total number of lepers of all races segregated at the end of 1918 was 2230, and the number of unsegregated lepers is estimated to exceed 1000. Malaria is endemic in parts of Zululand and of the Transvaal, and at times becomes epidemic over wider areas, but European settlements and increase of cultivation and drainage is circumscribing the areas where the disease is endemic. Plague was unknown before 1899, but since that date numerous small epidemics have occurred, chiefly traceable to rats in shipping from India and South American ports. Small numbers of deaths were reported almost annually from 1912 to 1921, but no infections in rodents or other animals were discovered. In 1921 the existence of epizootic plague in certain wild rodents in the Orange Free State was established. There have been many severe epidemics of small-pox since the introduction of the disease in 1713; after the Cape Parliament Public Health Act of 1883 was passed and vaccination became compulsory, the outbreaks have almost all been of the mild "amaas" or "kafir-pox," so called because natives are chiefly affected. Tuberculosis, widely disseminated when from about 1880 onwards tuberculous Europeans began to come out to the dry elevated highlands of the interior, is now prevalent among the coloured and native population. As regards sanitation, considerable attention has recently been paid to water-supply, sewerage, public slaughter-houses, &c., in most smaller towns and in many villages. Maternity and child welfare is attracting an amount of interest which has greatly increased during the last few years. Most municipalities and some other local authorities have health officers and departments attached to the local authority, which is responsible for control of sanitation, outbreaks of infectious disease, &c.; health and medical work, for which the Union Government is responsible, is carried out by means of medical officers known as district surgeons, a few of whom in large centres are whole-time officers, the remainder combining part-time Government work with private practice. In each seaport a port health officer is appointed by the Union Department of Public Health (established 1919) to carry on the health inspection and control of vessels, and to assist immigration officers, in an advisory capacity, with regard to the physical fitness of immigrants to enter the Union. Tuberculosis is specially cited as a disqualification, special permission being required for a person suffering from the disease to enter the Union. Other sections of the Year Book are as useful and accurate as is the chapter here summarised.

FOR an extension of Bury Infirmary, to take the form of a children's hospital and to serve as a war memorial, over £40,000 are in hand. About £10,700 will be expended on the building, and the balance, which it is hoped to raise to £30,000, will be devoted to endowment.

Post-Graduate Lectures

ON THE

URGERY OF THE THYROID GLAND.

Delivered at the London Hospital on June 8th and 15th, 1923,

BY A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON, LONDON HOSPITAL.

LECTURE II.*—EXOPHTHALMIC GOITRE.

THE problem of Graves's disease or exophthalmic ɔitre is even more difficult of solution than the roblems of colloid goitre or of simple adenoma. here are so many gaps in our knowledge of this ysterious disease that agreement is far from being ached as to its nature and cause. As McCarrison[21] as pointed out, there has been little or no study of its ɔidemiological nature, and although much is known the distribution of endemic goitre there is at resent no such knowledge of a similar distribution Graves's disease. In England there are two distinct ɣpes—those which supervene on colloid goitre, and ıose which start in previously normal people. The rmer is the less common, and in endemic areas ıch as Berne and the Gilgit and Chitral Valleys, arau and McCarrison[21] have shown that this variety distinctly rare. In it the ætiological factors of ereditary and general infection will be similar to ıose of colloid goitre, but in the primary variety ıey appear to have a less definite bearing.

PATHOLOGY.

Moebius[25] first put forward convincing evidence show that the disease was dependent upon excessive cretion of the thyroid. Since that time evidence as been accumulating that the symptoms are always ssociated with a change in the gland. From time time cases are described in which there is no sible enlargement of the thyroid, but, as Kocher[18] ıd Berry[4] have shown, no one has ever demonstrated ıat a case of Graves's disease can occur with a normal ıyroid. The size of the thyroid will vary consider-ɔly according to whether there has been a previous ɔlloid enlargement or not. To the naked eye three stinct varieties may be recognised, and it is well distinguish these since they are associated with somewhat different symptom-complex. For con-enience one may describe these three varieties as ıe colloid type, the vascular type, and the nervous ɣpe. The first variety has very similar character-tics to that of a colloid goitre. There is a much ılarged smooth mass which is semi-transparent from ıe presence of colloid, but on section there has been considerable proliferation of the epithelium, and ence the colloid spaces are not nearly so distinct ɣen to the naked eye. Remains of the distended esicles are, however, seen scattered throughout the ıt surface, and in some cases the cellular change ay not be sufficiently pronounced to be noticeable the naked eye, the gland then appearing to be simple colloid goitre. The vascular type, which is und more commonly in relatively young women, ıows also a smooth uniform enlargement of the whole and, but to a less degree than that which super-enes on a colloid goitre. The cut surface shows a ıiform granular or fleshy appearance, so that mani-stly it is richly cellular. Little or no trace of colloid ın be seen. The third or nervous type is a rather ıaller thyroid which is found more commonly in ople of a later age, generally at or about the meno-ıuse. Not only is the gland relatively smaller, ıt it is rather more irregular and nodular. The ıt surface has a much more lobulated appearance, that portions of the gland stand up and give mewhat the appearance of multiple small adenomata. ıey have, however, no definite capsule, although the ɔrous stroma is more in evidence and bands of fibrous tissue pass between the adenomatous masses. As with the vascular thyroid, each of these areas is finely granular and shows little or no colloid. All three varieties are extremely vascular. At operation they are found to have enormously dilated veins and very large arteries, and the cut surface bleeds with extreme freedom. The microscopic section shows a very characteristic appearance. A well-established case will show a very great cellular hyperplasia. So great will have been the proliferation of the cells lining the acini that in the greater part the gland will appear to be a solid cellular mass. Here and there, however, small acini can be seen. Even in these there is some proliferation of the epithelium with infolding of the walls of the acini. In these spaces there is a small amount of poorly-stained colloid. If the change has supervened upon a colloid goitre there will still be the large spaces containing colloid material, but there will be very considerable proliferation of the interacinar epithelial cells and some proliferation in the acinar walls with consequent infolding. The characteristic microscopic picture, therefore, is a great increase of the epithelial elements and the presence of only a small amount of poorly-stained colloid. Occasionally an exophthalmic goitre may be associated with an adenoma, a condition which must be sharply distinguished from the mild amount of hyperthyroidism which is found with a fœtal adenoma. That portion of the thyroid, apart from the adenoma, will always show much cellular proliferation, whereas the adenoma may be of the colloid type. In the fœtal adenoma the proliferation is limited to the encapsuled growth.

ÆTIOLOGY.

Like other diseases of the thyroid, this condition is much more common in females than in males. In my own series[31] there were 129 females and only 10 males—that is, a proportion of 13 to 1. Sir Hector Mackenzie[23] found in his series that the proportion was 10 to 1, and this is the figure usually accepted. Murray,[26] however, made the interesting observation that in his recent figures the proportion of males is increasing, for whereas in 120 cases up to 1903 the proportion was 10 to 1, in 300 cases between 1911–21 there were only three females to one male. He raises the interesting suggestion that as the modern male is becoming more highly-strung and nervous in character, so he may be becoming more prone to exophthalmic goitre. My own figures, however, have not shown any such increased tendency in the male, but my patients, being mainly drawn from the hospital out-patient department, may not have shown the degenerative effects of civilisation to so marked a degree. Heredity seems to be a much less important factor in this variety than in the others. In Sir Hector Mackenzie's series[23] there was some family history in 10 per cent. of the cases. This is considerably less than that of the colloid goitres, where even in this country some 25 per cent. of the cases have one or more members of their families affected.

The age-distribution is somewhat similar to that of a colloid goitre, and like the sporadic cases of that disease it is rare to find the condition in young children. Sir Hector Mackenzie[23] in his series found there was one patient of 10 years of age, the others were all over 14. Attention has already been drawn to the fact that two distinct varieties of the disease may be recognised, and this is also seen in the age incidence. The vascular type is much more common in young people, and in my own series accounted for about half of the cases, their age of onset being between 15 and 25. The other or nervous group is commoner at a later age and is generally seen commencing between 35 and 45. It is of interest to note in Sir Hector Mackenzie's series[23] that in his hospital cases half of the patients were under 25, whereas in his private cases less than one quarter began before this age. It would seem, therefore, that the more well-to do portion of the population are more prone to suffer from the nervous type. This may be due to the fact

---

[*] Lecture I. appeared in THE LANCET of July 14th, p. 53.

that such people are more subject to mental disturbance, which has long been noted to be a potent factor in the development of the disease. Very frequently one obtains a history that some severe mental stress, such as a shock or fright, or even prolonged mental worry, immediately preceded the onset of symptoms. During the late war a large number of cases of hyperthyroidism were seen in soldiers who had been exposed for a long period in the trenches, and in this country I have in my own series met with several cases who dated their disease back to a fright received during an air-raid. Sir Hector Mackenzie[23] found that in his series some serious mental disturbance was present in one-third of all the cases.

The relationship of an acute or chronic infection to this disease is not nearly so clearly established as in the case of colloid goitre. The researches and experimental work of Farrant[13] have, it is true, shown that after exposure to an acute infection or to an acute toxæmia changes occur in the thyroid gland which are identical with those seen with exophthalmic goitre. There is, however, as a rule, no clinical evidence of hyperthyroidism, and none of manifestations which are found associated with this disease. The relationships of intestinal infection cannot yet be regarded as proved, although McCarrison[21] believes that it is a very important factor. It is true that in many cases the symptoms date back to some acute infection such as influenza or rheumatic fever, but such a disease might act in much the same way as any mental disturbance rather than from the effects of the infection. Cases have been reported where the patient has been cured by methods directed to the improvement of intestinal stasis or the removal of some other source of infection such as may be found in the tonsils or teeth. Such cases are very few in number and it cannot yet be said that infection has been proved as a cause of the disease. McCarrison[21] has also laid stress upon the importance of malnutrition as a causative factor, but that such a condition is not an essential cause of the disease is shown by the fact that many cases occur in well-fed and otherwise healthy people, and there is no evidence at our disposal to show that the disease is more common among the poor.

CAUSE OF SYMPTOMS.

Much discussion has from time to time centred around the cause of the very diverse symptoms which occur with exophthalmic goitre. The older views that the disease was due to some lesion of the restiform bodies, which was based on the experiments of Filehne,[14] or of the sympathetic system, have little if any evidence to support them, and are now disregarded. The three views which are supported to-day are that the symptoms are due (1) to hyperthyroidism, (2) to dysthyroidism, (3) to pluriglandular disturbance. It will be manifest that whichever of these three theories is accepted, it will still leave unsolved the reason as to why there is a disturbance of the thyroid or of the other glands of the endocrine system. This change may still be caused by infection, by mental stress, or some other factor at present unknown. The belief that the symptoms are due to a pluriglandular upset has at first sight a considerable amount of evidence to support it. It is realised that in many cases of exophthalmic goitre and also of hypothyroidism there are changes in the pituitary gland and often evidence of interference with the activity of suprarenal glands. Moreover, the close relationship between the changes in this gland and periods of ovarian activity in the female will support this view. Strong evidence has also been brought forward to show that the thymus is as much or even more responsible for the symptoms as is the thyroid. Crotti and Bowen[9] as well as Capelle and Bayer[6] have strongly supported this view. All those who have had an opportunity of seeing post-mortem examinations upon examples of this disease will support Berry's statement[4] that in no such examination can one fail to notice an enlargement of the thymus. Bircher[5] states that he has been able to produc symptoms of the disease by grafting human thym tissue into the peritoneal cavities of dogs. Garre even advises operation upon the thymus gland as cure for exophthalmic goitre. Such views have no however, received general acceptance, and it is qui possible that the changes in the other glands of th endocrine system are secondary to those of the thyroi gland. The experimental and clinical evidence tha the symptoms are due to a hyperthyroidism is great that this view is generally accepted to-day, an it is upon its acceptance that the value of surgica treatment is based. The evidence may be summarise as follows: It has already been shown that Moebius, Kocher,[18] and Berry[4] have demonstrated that the are always pathological changes to be found in th thyroid in Graves's disease, even when the gland not clinically enlarged. A large number of exper ments have been carried out upon animals. Edmunds and Baruchi[3] were able to produce typical Graves disease in a large series of monkeys, dogs, rats, an rabbits by administrating large doses of thyroi obtained from ordinary human goitre. These result have since been confirmed by French.[15] Considerabl discussion has, however, arisen in the case of othe experiments because it is difficult to determin accurately how far symptoms produced in anima are really analogous with Graves's disease in me Klose, for instance, found that extracts of thyroi from cases of Graves's disease gave rise to differer symptoms than extracts of normal thyroid whe injected into animals, and Carlson[7] claimed that th symptoms which were produced were not those exophthalmic goitre. Hence these observers an many clinicians to-day believe that the symptoms exophthalmic goitre are due not so much to a hype thyroidism as to a dysthyroidism. The more recen experience of de Quervain[10] would seem to show however, that rats fed with the thyroid of exoph thalmic goitre show the same hypersensitiveness t a deficiency of oxygen as when fed with th thyroid of an ordinary goitre, only to a muc more marked degree. In addition to the exper mental evidence there is a considerable amour of clinical observation which supports this view and cases have been reported in which larg doses of thyroid extract have been taken and hav given rise to a typical picture of Graves's diseas Von Notthaft's well-known case[30] was one in whic a man took excessive doses of thyroid extract as cure for obesity and developed typical symptom Sir James Barr[2] reports others where sympton followed excessive doses of tincture of iodine, an many cases, including those reported by Ball Kocher,[19] and Pineles,[28] have been recorded of hype thyroidism following the use of thyroid extract i the treatment of simple enlargement of the thyroi The pathological work of Wilson[37] and MacCarty, who showed that the amount of cellular proliferatio was in direct proportion to the extent of the hype thyroidism, would support this same view. In th previous lecture stress has been laid upon the fac that adenomata of the fœtal type may give rise t symptoms of hyperthyroidism, and Dunhill[11] an Berry[4] described cases where similar symptoms hav occurred in association with parenchymatous goitr Any surgeon who has operated on a large numbe of thyroids will have met with cases where typical exophthalmic goitre has become grafted upo a colloid goitre, and will have found that in thes cases there is in addition to the colloid change definite proliferation of the thyroid epitheliun Symptoms of a similar nature may occur with carcinoma of the gland. A well-known example this is the case reported by Clunet.[8] The goo results which so often follow the operative remov of a portion of the enlarged gland lend very stron support to this view. It is true that many investiga tors, among whom may be mentioned Huber, hav laid very special stress upon the fact that certai cases fail to be cured by operative treatment. Tha this is so will be endorsed by all surgeons of experienc it it must be remembered that the amount of gland hich is removed at operation is very empirical, and is often necessary to remove an amount which is sufficient to cause a cure simply because a larger peration would be fraught with considerable danger. all large series such as those reported by Dunhill,[11] ocher,[20] and Halsted,[17] and I may say also in y own series,[31] there have been examples in which e first operation has caused only an amelioration. urther operation has been necessary, but with the ore extensive resection a complete cure has been tained. It may be said, therefore, that the balance evidence to-day strongly supports the view that the mptoms of exophthalmic goitre are due to a hyper-yroidism. It must be realised, however, that this not a full explanation of the disease, for although ere is a certain amount of evidence that this hyper-yroidism is itself dependent upon infection, our owledge of the cause of the hyperactivity of the yroid is at present incomplete, and although to-day erative removal may be the most satisfactory eatment, one is led to hope that in the future the use of the excessive activity of the thyroid will be scovered and will be corrected so that operation ll no longer be necessary.

SYMPTOMS.

The symptoms of this disease are manifold. The yroid itself is generally enlarged, but the extent of e enlargement will vary very considerably. It is ost in evidence in those cases which are secondary a colloid goitre, and here, indeed, it may be the mptom of which patients chiefly complain. In the scular type the thyroid is also considerably more larged than the nervous variety. Thus it is that a general rule the younger the patient the larger e thyroid, and indeed in some of the more elderly ses the gland may be so slightly enlarged that it is t palpable. These cases are often described as aves's disease with no goitre. The enlargement is a rule uniform, although one lobe may be slightly gger than the other. In a well-established case, pecially in the vascular type, the anterior and ternal jugular veins are prominent and pulsate ely. The rapid beat of the carotid vessels is very anifest, and in some cases an actual expansile lsation may be seen in the gland itself. Palpation the upper poles will nearly always reveal a definite rill, and in this position a murmur may be heard th a stethoscope.

There are usually very distinct ocular symptoms. e eyes are more prominent, the exophthalmos being en quite early in the disease. There has been much scussion as to what is the actual cause of the ominence of the eyes, but the evidence to-day, as irray[26] has shown, would seem to point to its ing largely due to an increase of intra-orbital fat. hatever is its origin, it is one of the last symptoms disappear when the patient is cured. Associated th the exophthalmos are certain physical signs. ellwag's sign is the presence of a visible ring of erotic around the cornea. Von Graefe's sign is the bility of the upper lid to follow the eye when it is ected downwards, so that if the patient looks down wards her feet there is a wider ring of visible erotic above the cornea. Moebius's sign is the bility of the eyes to converge in accommodating for ar objects, and Joffroy's sign is the failure of the ehead to wrinkle when the patient looks up. Less nmonly there may be weakness of the ocular iscles, so that there is slight dropping of both upper elids, and occasionally even paralysis of one or other ternal rectus, giving rise to double vision. It is portant to remember that when the proptosis is treme the patient may be unable to close the eyes, d under these circumstances the cornea may erate, so that in many advanced cases there has en an extreme ulceration going on to sloughing of cornea, with perforation and even complete struction of the eye.

The circulatory symptoms are always a feature of the ease. The patient quite early in its progress will complain of palpitation and dyspnœa, which is always greatly increased on exertion or excitement. It will be found that the pulse is raised to 110 or 120 per minute even in mild cases. In the more severe periods of the disease it is often raised to 160 or sometimes, indeed, may be uncountable. Even at this period it will be noticed that the heart's apex beat is displaced outwards and is very forcible, so that it is diffused over a large area of the thorax. At first the sounds are clear in spite of the heart's rapidity, or there may be characteristic hæmic murmurs. Later on the cardiac muscle suffers, so that the pulse becomes irregular and there is evidence of auricular fibrillation. In several of my more advanced cases Dr. J. Parkinson found an advanced stage of this condition, a change which will only improve to a slight degree even when the hyperthyroidism is brought to an end.

The skin and its appendages also show very definite changes. These patients are prone to flush on the slightest exertion or excitement, and when first seen often show a characteristic appearance owing to the irregular and blotchy erythema of the face and neck. The sweat-glands are nearly always over-active, the constant moisture of the skin causing the patients considerable annoyance. They stand the heat badly and nearly always much prefer the winter months of the year. It is important to recognise the evil effects of heat, not only in causing an exacerbation of the disease, but because of the increased risks of operating during the hotter periods of the year.[31] Later on in the disease there are nearly always pigmentary changes, small irregular patches of dark-brown pigmentation appearing on the arms, chest, and abdomen. They are more marked in that frequently the patient shows a certain amount of general anæmia. The appendages of the skin are also affected. Nearly always these patients will complain of their hair falling out, and I have observed several cases in which there have been patches of alopecia appearing both before and after operation. In some cases this condition has progressed until very nearly complete alopecia has resulted. Dr. J. H. Sequeira has called special attention to this condition.

The above group of symptoms are most marked in that variety of the disease which I have described as the vascular type. These patients are usually relatively young. The condition has frequently started shortly after puberty. They show considerable enlargement of the thyroid gland, advanced exophthalmos, a rapid pulse, and very increased sweating. The other symptoms about to be described are also present, but, with the exception of amenorrhœa, are less in evidence.

Nervous symptoms are always present to some degree, and may indeed be the first indication of the onset of the disease. Some of these patients have first noted that they were startled and excited when spoken to, and at times indeed the first changes noticed may have been that they showed a tendency to drop articles when carrying out their household duties. They are always manifestly upset by the medical examination, and often have a difficulty in giving an account of their symptoms. This nervousness has been specially noticed in those cases of slight hyperthyroidism found in soldiers after long exposure to trench warfare, who later developed other evidence of hyperthyroidism. There are also well-marked physical changes on the nervous side. The patients show a fine rapid tremor in the extended hands. It affects, however, the whole limb and is present in the extended tongue. Sometimes it may be sufficiently marked to interfere with the patient's work. The threading of a needle and even drinking fluid from a full cup may be impossible. The tremor, like the other symptoms, is always increased when the patient is worried or excited. As further evidence of change in the nervous symptoms it may be noted that these patients often have bad dreams at night which are sometimes indeed sufficient to interfere considerably with their sleep. In the nervous type of the disease this group of symptoms is always the most in evidence. These patients may show such nervous irregular movements that they can barely sit still, and the condition comes to resemble closely the movements of chorea, although the more advanced age of the patient —she is usually between 35 and 40—will aid in the diagnosis. Mental changes are also more marked. In the minor degrees the patient is simply abnormally irritable, excitable, and emotional. These changes may be sufficient to interfere with her work, and she finds that they are more marked after a heavy day's work. It is often, indeed, on account of these symptoms that she has to abandon her business. Occasionally the condition may spread even further, and hallucinations may supervene. She then becomes melancholic or even maniacal, and attempts at suicide are not uncommon. In such conditions the patient will often complain of severe headache.

Gastro-intestinal changes are, as a rule, an indication of an exacerbation of the disease. There are periods often at the onset or perhaps arising irregularly at no definite time, and being dependent upon no known cause, when the patient will have severe attacks of vomiting and diarrhœa. At such a time the other symptoms will usually increase. As the exacerbation dies down the vomiting and diarrhœa will cease, and the patient will then develop a good appetite, which, however, at times may be capricious. It is in such periods that she loses considerable weight, and, in a severe case of the disease, wasting, passing on even to profound emaciation, is a constant factor. It has been noted that in some of these periods when the patient has shown diarrhœa and vomiting that there is glycosuria. The relationship of Graves's disease to diabetes has indeed often been noted, and it would seem that even when the hyperthyroidism has been relieved by operative treatment the patient is still prone to develop diabetes. In my series of 139 cases there were two who developed diabetes at periods of one and five years after operation. The relationship of these two diseases has been investigated by Williamson,[36] and he has shown that diabetes may follow the Graves's disease or rarely precede it, or that both diseases may develop together after some mental shock. He has also shown that not only is there often a mild temporary glycosuria in Graves's disease, but, as a rule, the sugar-tolerance is diminished. Occasionally there is a very definite family history of diabetes in patients suffering from Graves's disease.

Changes in menstruation are very common. A large proportion of my younger patients with the vascular type of the disease have had complete amenorrhœa, but this symptom is not constant, for in some of the more advanced conditions the periods have been quite regular and normal. It is usually stated that exophthalmic goitre has no effect either in preventing or altering the course of a pregnancy. This has not, however, been my experience. Some of my cases who have been married for several years and have been childless have become pregnant shortly after an operation. Moreover, it has been my general experience that if a pregnancy has occurred in unoperated cases the symptoms have always been considerably exaggerated, and I have therefore come to regard pregnancy as having a very deleterious effect upon the course of the disease. In those cases who have shown amenorrhœa the return of menstruation is often one of the earliest symptoms of improvement after an operation.

Changes in the blood have frequently been described as characteristic of the disease. As a general rule there is a slight amount of secondary anæmia. Kocher[18] has laid very great stress upon the presence of changes in the differential count of the white corpuscles, and states that there is nearly always an increase in the lymphocytes. Dr. Panton has, however, examined a large number of my cases and has not been able to determine that a change of this sort is in any way characteristic.

TREATMENT.

It is customary to-day to compare the results
medical and surgical treatment and to sum up i
favour of one or the other. It must be remembere
however, that at no time has there been a clos
coöperation between medicine and surgery, and i
no disease is such coöperation so essential as i
exophthalmic goitre. My aim, therefore, will be t
indicate to you how the two methods should b
combined and which variety of case should be treate
with or without surgical measures. It is still perha
necessary to point out that medical treatment alo
cannot be considered satisfactory for the treatme
of all cases. I think this is now becoming unanimous
recognised. Sir Hector Mackenzie some 10 or 1
years ago pointed out that with medical treatme
the mortality was somewhere in the region of 25 p
cent., and that even in those cases which did not d
medical treatment had to be carried out over a cour
of very many years. At that time, however, he di
not advocate surgical intervention, as he regarde
the mortality of operative treatment as much t
high. In his more recent communication[24] his vie
have entirely changed, and he is now one of t
strongest supporters of operative treatment. T
evil results that may accrue in long-neglected cas
I have already mentioned, and you are probab
all familiar with examples of such. Grave myocardi
changes, severe mental disturbances or injury, a
destruction of the eye may all result, and once havi
arisen will usually be beyond recovery even if t
hyperthyroidism is overcome. Since the view
usually accepted that the disease is due to hype
thyroidism the rational form of treatment wou
seem to be the removal of the excess of hypertrophie
gland, but, as I have already pointed out to yo
such a form of treatment must be regarded in its
as unsound. It is only a temporary measure whi
will be abandoned when the cause of the hype
thyroidism is known and can be overcome. The on
serious objection to such a form of treatment to-d
is that of the mortality of the operation. Only a fe
years ago this was extremely high, and there is
doubt that even to-day such an operation is one whi
has to be undertaken with the greatest care. It
always associated with considerable anxiety, for t
causes of a temporary exacerbation of the hype
thyroidism are but little understood. More rece
series of statistics show, however, that extreme
satisfactory results can be obtained. In the discussio
at the Royal Society of Medicine in 1921 it w
agreed that the present mortality averages son
5 per cent. In individual series which have be
published the mortality has been reduced considerab
below this. Romanis[29] published a consecutive seri
of 250 cases with only a 2·4 per cent. mortalit
Pemberton[27] has published the latest group of cas
from the Mayo Institute comprising in all 1093 case
In this group the mortality was 1 per cent. O
may say, therefore, that in this condition the dang
is no greater than that associated with any oth
major operation. The difficulties arise in mo
advanced cases where severe secondary changes ha
taken place, and in hospital statistics a large numb
of such cases will have to be included, for althou
the risk may be well recognised, operation may
the only possibility of holding out any hope
amelioration or cure. It is the inclusion of a lar
number of such advanced cases which has kept t
mortality of my own series at about 5 per cent., a
I believe that if it fell much below this figure it wou
be an indication that I was refusing to offer help
many of those patients which stood most in need of
It must be agreed, therefore, that surgery is not fr
from risk, but that it has a very definite place in t
treatment of this condition, and we have to consid
carefully what are the indications for its use. T
points I would lay stress upon in operative treatme
are :—

(a) *Selection of Time of Operation.*—It is my custo
never to operate in the first six months of the disea

elieve that in this period medical treatment holds t the greatest hope of success. In the early stages symptoms are sometimes very acute and rapid their progress. Not only will an operation in such case be fraught with considerable risk, but the ient will generally react well to medical treatment. e details of such medical treatment it is not my ce to discuss with you, but there is one method ich must be mentioned as much attention has been ected to it of late. This method is that of X ray atment. My own experience of its use has been y unsatisfactory. I have knowledge of three ups of cases in which it has been applied. There firstly those who have come to me seeking further vice but have already had such a form of treatment. nifestly these are selected cases of failure and refore it would be unfair to judge the results of ray treatment upon them alone. In my series of cases there have been 14 such. They have all l prolonged courses of X rays and have gained le or no benefit. A large number of them indeed, you will see from the photographs,* have been y seriously scarred and burnt from the application the rays. Two stated definitely that their sym- ms were much increased after treatment, one of m developed a squamous carcinoma of the skin ich, although removed at the same time as the ration upon the thyroid, later recurred and led the death of the patient. A second group are se who in the earlier series had been treated only h a hemithyroidectomy and who had had some urrence of symptoms with enlargement of the aining portion of the gland. Such conditions uld seem to specially lend themselves to treatment X rays, but of five which have been so treated re has been no relief in any example. Of the ue of this form of treatment in the very early ges where an operation is not indicated my erience is naturally small, but I believe that, if nbined with other methods, it may be of some value. ave no evidence that X rays can overcome hyper- roidism even to the point of myxœdema, as is netimes claimed; but, on the other hand, I have er found that it makes a future operation more icult on account of the fibrosis. If I had evidence t it produced any fibrosis I should believe that it ld control the hyperthyroidism. I have never n it produce any change in the thyroid, but it y cause dangerous and unsightly changes in the n. If at the end of six months the benefit has n very slight, or if the symptoms return as soon he patient ceases medical treatment, then surgical rvention should be considered. Even if opera- has been decided upon, an enormous improve- nt in the immediate results will be gained by a eful selection of the time of operation. It is well ised that all cases of exophthalmic goitre show iods of considerable exacerbation. Sometimes se are most marked in the first six months of the ase, but even later there is always a periodic iation. Mayo has stated that there has been rly always a second relapse at the end of the first r which would usually last about six months, and t such a time was bad for operation. I have not nd in my series that this change is at all constant that every case is liable to bad attacks lasting for rt periods which depend upon no known cause. The safe method of treatment, therefore, is to care- y watch each case and to operate when the sym- ns are minimal. It is well known that any sudden nge of scene or excitement will lead to an exacerba- , and therefore no case must ever be operated n immediately after the patient is admitted to pital or nursing home. They should be carefully ched until it is realised from a study of the pulse temperature, and often of the basal metabolic , that the patient is in the best possible condition the operation to be undertaken. It is during this od that medical treatment is of so much value. In a large number of my more recent cases I have had the great benefit of Dr. C. H. Miller's help. He admits such cases and gives them a course of carefully thought-out medical treatment. If progress is marked operation is delayed, but if, as so often happens, the patient improves considerably and the condition then remains constant, the best time is selected and an operation is performed.

In the late stages of the disease, where there are secondary changes in heart and kidneys, an operation could only be performed with considerable risk, and the mortality is certainly high, but on the other hand, unless an operation be performed, progress will be steadily downhill and the disease itself is likely to be fatal. The increased dangers, therefore, are no counter-indication to operation, but the risk must be carefully explained to the patient's relatives. Although such patients are unlikely to be completely cured, they will often be so enormously improved that they will be converted from bedridden wrecks to those who are able to lead a useful happy life. In spite of all the above precautions there is still an element of uncertainty about this disease, and both Dunhill [11] and Berry [8] have had an experience which is similar to my own—namely, that every operation is carried out with a certain amount of anxiety, for even in those cases which appear to be most suitable an unlooked for result may occasionally occur. This indicates that there is still some factor of which our knowledge is at present imperfect. I[31] have recently laid stress upon the fact that during the very hot weather the symptoms are all exaggerated and the patient stands operation very badly, and that therefore during a heat wave the operation should be postponed.

(*b*) *Selection of the Type of Disease.*—I have already drawn attention to the different types of disease which may be met with, and the importance of recognising them lies chiefly in the fact that the mortality of operation differs considerably in each type. The colloid and nervous types are those who are likely to show the lowest operative mortality, but even with them the precautions mentioned above must be carefully observed. The nervous type of patient stands an operation badly, so that a rather more prolonged preliminary treatment may be necessary. Should there have been a history of mania or of attempts at suicide the outlook is even more serious, and for this reason many physicians and surgeons advise that the presence of such symptoms should be regarded as definite counter-indications to operation. It should certainly never be considered until medical treatment has been tried, but I have one case in my series who on three occasions had attempted suicide but after operation enormously improved and is now living a normal and happy life. An operation under such conditions must only be undertaken after the risks have been carefully considered and explained to the relatives.

(*c*) *Preparation for Operation.*—The importance of a thorough course of preliminary medical treatment has already been mentioned. It should under no circumstances be omitted. The administration of large saline injections as a means of lessening the toxæmia is of considerable value and may be very useful as a preparation for the anæsthetic. In the choice of anæsthetic there has been much discussion. Many surgeons lay great stress upon the importance of a local anæsthetic. It has been my custom, however, to use a minimum amount of ether, as I believe that if this anæsthetic is carefully given it is practically free from risk and it overcomes the drawback of the psychical disturbance which is often so evident in these patients when they are conscious. My own method is to administer for several days before the operation a rectal saline. On the day of operation the rectal saline is changed for a mixture of olive oil and ether, 3 oz. of each being used. This is administered about three-quarters of an hour before the operation and is usually sufficient to cause unconsciousness, so that the patient can be carried to the theatre without her knowledge. The actual anæsthetic is continued with ether on an open mask, but as a rule only about 1-1½ oz. is required. Chloroform in any form must never be used; it appears to act as a deadly poison.

---

* Many photographs of cases before and after operation were n at the lecture.

(*d*) *Choice of Operation.*—Many forms of operative technique have been carried out. In some advanced cases a preliminary ligature of the vessels of one or other pole—and my own belief is that ligature of the upper pole is a much simpler and less serious operation—is of value in reducing the toxæmia. If, however, a careful course of medical treatment has been carried out this preliminary operation will be required very seldom. There is no doubt that at the operation itself the two chief dangers are dependent upon pressure upon the gland and upon hæmorrhage. Owing to these dangers the operation must be slowly and carefully performed. Every vessel should be carefully ligatured before it is divided, and any attempt at a wedge-resection should be abandoned. It will generally necessitate considerable pressure upon the gland, a much more severe hæmorrhage and rather rougher handling in order to control the bleeding.

(*e*) *Operative Technique.*—Free access to the gland is obtained by means of a collar incision, and for the same reason the pretracheal muscles should preferably be divided. The individual vessels are isolated in turn and divided between ligatures. The number of vessels to be tied and the amount of thyroid to be removed will of necessity vary with the severity of the case, and if the symptoms are very marked it may be necessary to be content with a small resection, and later, when the patient has improved, to carry out a further operation. My aim in suitable cases is to ligature and divide the superior vessels, the middle and inferior thyroid vein in the right side; to ligature and divide the left inferior thyroid vein, and to ligature the left superior thyroid vessels. These steps are accomplished in turn; the right lobe is then turned inwards, and the inferior thyroid artery ligatured in continuity as it lies on the longus colli muscle. The right lobe, except for a small slice on its posterior surface, is then removed together with the isthmus and the inferior and the internal portions of the left lobe. There is thus left the upper and middle portion of the left lobe, the superior vessels of which have been tied, and which is, therefore, supplied by the inferior thyroid artery and drained by the middle thyroid vein. After all bleeding has been controlled a tube is inserted and the pretracheal muscles are closed. The skin is sutured with silkworm gut.

(*f*) *After-treatment.*—After every operation upon the thyroid gland there will be a period of reaction, probably due to hyperthyroidism, and in this period danger arises. In fatal cases the patient will get more and more restless, the temperature and pulse will rapidly rise, sweating will be increased, and there will often be a condition of slight mania. In satisfactory cases the temperature may rise to 102° and the pulse to 140 or 160. As long as there is any such evidence of reaction the tube should be kept in place. Morphia should be given freely to overcome restlessness, and large quantities of fluid administered both by mouth and per rectum. The patient should be kept in bed for at least three weeks after operation, and after leaving hospital should be given strict rules as regards her life and diet. All form of excitement and stimulants should be avoided. The patient should live as much as possible in the fresh air, and a plain, simple diet with a relatively small amount of meat should be advocated.

Post-Operative Results.

It has been mentioned that in my own series the mortality has been 5 per cent. This probably could have been reduced, for in some of the earlier cases the operation was performed at what is now realised to be an unsuitable time. Until, however, these cases come up for treatment earlier in their disease, and until operation is sought before there are advanced secondary changes, there will still be an appreciab mortality. Of the cases that survived operation fi have died later; one of these was from the recurren of X ray carcinoma, two had developed diabetes, ar two had succumbed with cardiac symptoms due hyperthyroidism. Of the remaining 129 cases, per cent. have been changed from disabled wrec into people who are capable of living normal lives ar of earning their living. In these, it is true, some st show exophthalmos, and have a pulse-rate which likely to be increased upon excitement and exertio but they are nevertheless able to live normal and hap lives. It must be remembered, too, that exophthalm although it will ultimately disappear entirely, m persist for a very long period, even when all oth symptoms have disappeared. It should also explained to the patients that after such an operati there is no immediate cure such as occurs with many other surgical lesions, and the following stag can be recognised in every case:—

(1) *Stage of Reaction.*—This lasts for three to fo days after operation, and the symptoms are those hyperthyroidism.

(2) *Primary Improvement.*—When the patient leav hospital it is often found that the pulse has fallen normal, that the tremor has almost disappeared, ar that there has been a remarkable and startli improvement. It will persist, as a rule, for two three weeks.

(3) *Stage of Relapse.*—Whatever rules are given the patients, it will usually be found that after th have returned home there is a certain return of the symptoms, and unless this relapse is appreciated will be found to cause considerable disappointme As a general rule it would last for only two to fo months, but if the case is less satisfactory, or if insu cient thyroid have been removed, it may be prolong very considerably, and, in fact, until a further porti of the enlarged thyroid is removed.

(4) *The Stage of Apparent Cure.*—It is only wh cases have been watched very carefully for a prolong period that it is realised that after operation th will show a complete freedom from all symptoms, b should there be any severe mental upset or disturban the symptoms may recur. I have had experience several such cases, apparently absolutely cured, w having been subjected to the disturbance and fear an air raid, have had their symptoms return to minor degree. As a general rule a short course medical treatment was sufficient to overcome the symptoms. This period of instability would appe to last for some two to four years.

(5) *Stage of Complete Cure.*—This is the conditi in which the patient is not only completely free fr all symptoms, but can apparently be subjected all normal shocks and disturbance without fear recurrence.

There is a general fear, since some cases show regression of the changes in the thyroid when und medical treatment, that similar changes might occ after operation, and since a relatively small porti of thyroid is left therefore myxœdema would resu I have no experience of any such complication. my own series of true exophthalmic goitre there h never been any myxœdema after operation. Koche has had a similar experience, and it would seem that the few cases reported the myxœdema appeared ve shortly after operation, and was due to removal of t large a portion of the gland. I believe, therefore, th this danger is greatly exaggerated.

It will be evident to you that in the treatment o very large number of the different forms of goitre have advocated the use of medical measures. I fe however, that no apology is needed for discussing subject which is so largely medical, for the first less that you as surgeons have to learn is what cases shou be so treated. If I have been able to indicate to y when not to operate as well as when to operate lesions of the thyroid gland, I shall feel that I have n taken up your time in vain.

(*Continued at foot of next page.*)

THE ÆTIOLOGY OF KALA-AZAR AND TROPICAL SORE.

BY B. BLACKLOCK, M.D. EDIN., D.P.H., D.T.M.,
DIRECTOR, SIR ALFRED LEWIS JONES RESEARCH LABORATORY, SIERRA LEONE, WEST AFRICA.

THE theory which associated kala-azar with the bed bug, and which promised well in the initial experiments carried out by Patton[1] does not, up to the present, appear to have yielded definite results; the position with regard to other insect vectors incriminated in this disease and in tropical sore is also unsatisfactory. The fact that the common bed bug has a very wide distribution has been adduced with reason against the theory that it would prove to be the vector of a disease of such circumscribed distribution as kala-azar. In investigating these diseases, attention has been given to the flagellates which commonly infest various plant bugs, but these have been exonerated on account of the fact that the bugs do not bite man. An observation which I recently made in Sierra Leone may possibly serve to focus attention again on plant-feeding bugs.

Since Lafont's[2] discovery of the occurrence of flagellates of the genus Herpetomonas in plant juices—the latex of Euphorbia—more attention has been given to the flagellates which infect plant bugs, as well as to the natural flagellates of other insects. Laveran and Franchini[3] recorded their success in producing Leishmania forms of parasite in mice by injecting them with flagellates from insects; Fantham and Porter[4] and other observers have repeated and confirmed their experiments. Recently Roubaud and Franchini[5] obtained in mice infection with Leishmania forms of parasite by allowing fleas having a natural infection to breed in their box. The infection, which proves fatal to the mice, was conveyed to fresh mice by means of subcutaneous injection of ground-up tissues. These workers also obtained a similar result in mice by injecting into them the fæces of fleas.

Flagellate Infection among Plant Bugs.

The occurrence among plant bugs of flagellate infection has been emphasised by Patton[6], who described *Herpetomonas lygæi* and other such bug flagellates. Evidence is also available of the ability of the flagellates to infect the bugs, not only in the alimentary canal, but also in the salivary glands. Franchini[7] reports that he has cultivated flagellates *Herpetomonas pyrrhocoridis* from the alimentary canal and salivary glands of *Pyrrhocoris apterus*. Miss Robertson,[8] in Uganda, found the alimentary canal of the red cotton bug infected; she also found that another species of bug, *Leptoglossus membranaceus*, was commonly infected with Herpetomonas in the salivary glands. She refers with emphasis to "the independent development in a sucking insect of all the factors requisite for the transmission of a flagellate, parasitic in the intestine, by way of the mouth parts of the insect host."

Experiments of great interest were carried out by Franchini[9] in cultivating in media containing plant juice various natural flagellates of insects. He showed not only that such flagellates will develop readily in certain of these media, but also—what is of especial interest—that the parasite of tropical sore will grow in a medium containing certain plant juices. There is thus established a connexion biologically between a human parasite and the insect flagellate and plant juice, which I venture to think is not without significance. If we find that bugs, which as a rule live on plant juice and which are capable of harbouring flagellates in their gut and in their salivary glands, are able to bite man, it would be a strong argument for the thorough investigation of the habits and bionomics of such forms before their dismissal from consideration in connexion with kala-azar and tropical sore.

Do Plant Bugs Bite Man?

I desire here to draw attention to the fact that a cotton stainer, which is apparently restricted very closely to certain species of food plant, is capable of biting man. The species* of bug is *Dysdercus superstitiosus*, which at first, as the result of several experiments made by me in the laboratory, I concluded could not bite man. This year at Freetown I was bitten by this bug on the ankle on two occasions, April 24th and 26th, while sitting out of doors at dusk, and after many attempts was successful in getting one to bite experimentally. On each occasion there was a local reaction in the form of an irritating swelling, and on the third occasion this was followed by extensive swelling of the leg, with considerable œdema and great itching. There was no general reaction, no rise of temperature, no enlarged glands; no parasites were found in the blood, but there was great eosinophilia. This species of bug has been observed by me to feed in nature on the carcass of a dead frog. A near ally, *D. fasciatus*, has been recorded by Mansfield Aders[10] as feeding with avidity on fresh mammalian carcasses, skins, and skulls. Lamborn[11] says that during the dry season *D. superstitiosus* appeared to thrive on almost any

---

* Mr. Lang, of the British Museum, kindly identified the species for me.

food of animal or vegetable origin, for eight or ten were noticed feeding on a dead and sun-dried lizard, and a batch of young nymphs were found on sheep's excreta. Peacock[12] gives an observation of young stainers of the same species feeding on a dead snail. The habits as regards food plants of these bugs confine them chiefly to cotton, the silk cotton tree, okra, and other Malvaceæ. While the obvious adaptability of such bugs makes it appear possible that in some districts they have acquired even greater readiness in biting man in nature, there is also the fact that they are in most cases very restricted either to certain areas or to certain food plants. On dissection of specimens of *Dysdercus superstitiosus*, I found that they were heavily infected in various portions of the alimentary canal with a Herpetomonas ; this was also found in one case in cœlomic fluid.

I believe these observations to be worthy of record, although owing to their having taken place only a few days before my leaving Freetown, they are necessarily far from complete. In view of the present state of the kala-azar problem, I consider that they indicate the necessity of an investigation of all such forms, not only in countries where kala-azar abounds, but also in countries where tropical sore occurs.

Note.—In a letter received, since this article was written, from Dr. Maplestone at Freetown, he informs me that he has discovered infection of the salivary glands.

KÖHLER'S DISEASE OF THE TARSAL SCAPHOID.

By H. H. GREENWOOD, B.S.Lond., F.R.C.S.Eng.,

CONSULTING SURGEON, G.W.R. HOSPITAL ; HONORARY SURGEON, VICTORIA HOSPITAL, SWINDON.

Since Köhler showed his first three cases of this disease at Wiesbaden in 1908 and published an account of them,[1] the number of examples placed on record is inconsiderable. In 1915, when he reviewed the subject, there were only 26 ; since that time additional cases have been described by Maynard Heath,[2] O'Brien,[3] Hetzel,[4] Moreau,[5] Roederer,[6] Beltrandi,[7] but the disease must still be considered to be comparatively rare. The symptoms and physical signs are not obtrusive, spontaneous recovery seems to be the rule, and the precise diagnosis rests on the characteristic X ray appearances ; it is probable, therefore, that the disease often escapes detection and that it is more common than the records indicate. The clinical picture is fairly clear-cut, although in details there are some differences of opinion.

Clinical Picture.

The disease occurs in young children, more frequently in boys, between the ages of 3 and 10 years. The onset is usually insidious, sometimes sudden,[8] with pain and swelling in the region of the tarsal scaphoid. Whilst it is generally unilateral, both feet are sometimes affected. The general health is usually indifferently good. The child develops a limp and shows more or less tendency to flat-foot. Spontaneous recovery always occurs, so far as present records show, in from 6 to 12 months from the date of diagnosis. The ultimate diagnosis rests on the X ray findings. On these, but not on their general interpretation, there seems to be general agreement. They are as follows.

(1) The affected bone is smaller than normal (half to quarter size) ; (2) the outline of the bone is irregular (Köhler omits to mention this fact) ; (3) the density of the bone is increased (estimated at two to four times) ; (4) the normal architecture of the bony trabeculæ has disappeared. To these may be added (5) the general shape of the scaphoid is altered, being more flattened from before back and not widened from side to side.

Ætiology.

When we consider the ætiology we find considerable diversity of opinion ; the attempt to find analogues in Madelung's deformity of the wrist-joint, in Perthes's disease, in Schlätter's disease of the tibial tubercle, would be more helpful if the ætiology of these affections were less speculative. Kidner's report of a case of Perthes's disease, in which at an operation " a *Staphylococcus aureus* from a blood-stream infection " was found, is suggestive, but lacks confirmation. All authorities exclude rickets and syphilis as causative factors ; most writers reject tuberculosis on grounds that appear inconclusive. Abrahamsen [illegible] strengthens the view that the disease is a simple " dystrophy " by citing the case of a boy aged 7 years, who without any (known) antecedent injury developed weakness of the right ankle. A skiagram showed that there was little or no sign of ossification present in the right scaphoid, although this process normally begins in the fourth year. In the left foot ossification was normal. After nearly three months' administration of thyroid extract a skiagram revealed typical Köhler's disease of the right tarsal scaphoid with a narrow, compressed, and dense centre of ossification.

Köhler himself shares this view, which receives confirmation from the fact that the disease may be bilateral (Köhler, 10 cases out of 26) and unassociated with any history of trauma. He also found a similar condition in the patella of the same side in one case. Rotch[10] found the twin brother of one case with similar X ray evidence in the scaphoid, but with no symptoms. The argument that the disease is a dystrophy is materially weakened, however, by Köhler's assertion that relapse sometimes occurs. Incidentally, his estimate of the duration of the disease at 2–3 years is shown by later observers to be too prolonged—in Maynard Heath's case,[11] as in mine, the bone had returned to an almost normal appearance in six months. Stümme[12] ascribes the disease to a compression fracture, and Preiser[13] supports his view by comparing it to a fracture of the carpal scaphoid. O'Brien[14] invokes a delay in ossification, stimulated by trauma to osteogenesis. Schultze[15] obtained a definite history of injury in six out of seven cases. Pfahler[16] dismisses injury on the ground of there being in many cases no history of such a cause and of the onset being often gradual. The latter assertion is generally conceded, and any injury is often so trivial that none can be recalled, but gradual onset and trivial injury as a provocative cause of tuberculous disease in the subject of a latent infection suggest more serious consideration of the view of Fassett,[17] who, so long ago as 1914, advanced the explanation that the lesion is a healed and sclerosed tuberculous infection.

The Question of Tuberculosis.

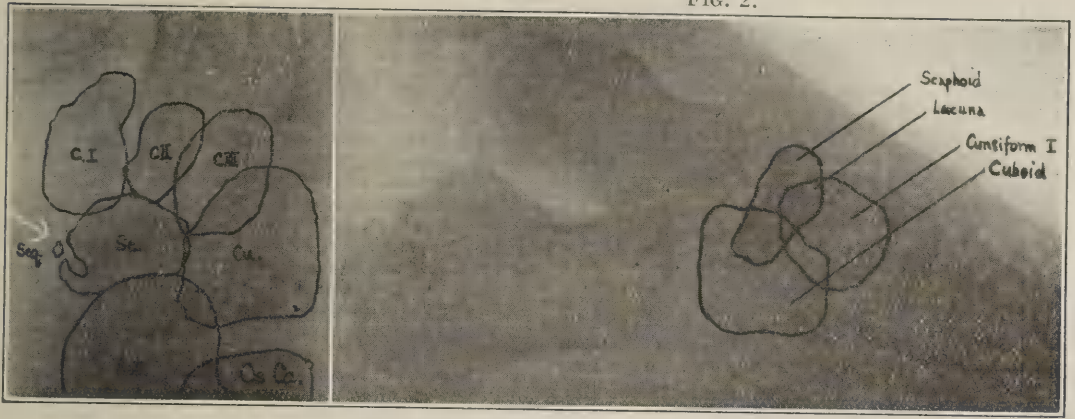
Although most authorities demur on account of the clinical course of the disease, and Hetzel[18] found the von Pirquet reaction negative, the new evidence I shall detail warrants a review of the clinical data and X ray appearances, none of which is incompatible with this theory. Dogmatic statements only serve to darken the night of our doubts, and should not be allowed to carry conviction.

Roederer,[19] reviewing the subject in 1920, asserts confidently that " les deux sexes sont indifférement atteints." (Maynard Heath declares that the condition is *always* found in *boys* between 3 and 9 years.) Again, he says, " aucun de ces enfants n'est tuberculeux." And later he states " deux fois seulement l'enfant appartient à une famille tuberculeuse (Köhler 1, Schultze 1)." As to the positive grounds upon which the assertion that all the patients were free from tuberculosis is based, there is no evidence. Parental berculous infection plays a more conspicuous part in e recorded cases than Roederer admits; in Maynard eath's case the father was tuberculous.

Let me quote from the excellent description of a se recorded by Dr. Giovanni Beltrandi.[20]

Boy, aged 6½ years, of healthy parents. The mother states at about two years prior to admission to the hospital the y had a fall, hurting his foot, with the result that he was me for some time; occasionally, at long intervals, he mplained of pain in the left foot, lasting for about an ur. Nothing untoward could be established until, two eks before, she noticed that the foot was swollen, while e pain was more severe than usual. On examination, on e dorsal and internal aspect of the left foot an irregular otuberance was observed, extending from the tibio-tarsal e to the metatarsic tarsus. The skin over this protuberance esents a very marked venous network. The circumference the left foot, measured over the protuberance, exceeds by cm. that of the right foot. The swelling is sensitive to essure, and all active movements of the foot are reduced.

FIG. 1. FIG. 2.



Right tarsus, (1) from above; (2) external aspect. Seq. = sequestrum; C.I, II, II = internal, middle, and external cuneiform bones: Sc. = scaphoid; Cu. = cubiod; Ast. = astragalus; Os Ca. = os calcis,

X ray examination of the foot showed that the scaphoid ne was reduced in volume to one quarter of the normal e. It also appeared to be divided into two parts; in the aller of the two the cortical and spongy substances show line of demarcation, and the pronounced shadow points the fact that there is a marked increase in the content of calcium salts in the scaphoid. In the larger portion the sence of any osseous organisation was also apparent. e scaphoid of the right foot also exhibited the same picture, not in so pronounced a degree.

A Case of the Author's.

In the following case the chief features will be found be similar.

male child, aged 5 10/12 years, was active but had ays been delicate. His mother was delicate and his father suffered for years from definite pulmonary tuberculosis. out Dec. 10th, 1919, the boy sustained an injury to his ht foot. Soon afterwards he fell ill with chicken-pox. ring convalescence he complained of pain in the right t, and on attempting to walk displayed a well-rked limp.

ondition on Examination.—Early in February, 1920, he referred to me. He was at that time pale and frail-king, but alert and intelligent. He limped obviously on right foot, which showed a swelling over the region of scaphoid bone, most marked on the dorsum of the foot. skin over the swelling was thin and smooth with increase the venous network. Pressure on the swelling caused n, but no œdema was present. Movements at the tarsal joint were limited.

Ray Findings.—A tentative diagnosis of early tuberculous ase of the tarsus was made and skiagrams taken. These wed all the stigmata of Köhler's disease. In Figs. 1 and 2 scaphoid bone of the right foot is seen to be smaller than mal, narrowed antero-posteriorly, irregular in outline, density of the bone much increased, and the normal hitecture blurred. In Fig. 1, however, there is a new ture, not observed in the record of any previous case—nely, a tiny sequestrum (indicated by an arrow) no larger n a millet seed, lying in the soft tissues, supero-internal the scaphoid. In the latter bone there is a deep hollow ch larger than the sequestrum, and from which the latter evidently been discharged. In the photographs taken five months later (July) the hollow had become a cleft, with the opening on the surface of the bone showing [illegible] mere dimple; the density of the bone has become less marked, and there was an increase in the thickness of the bone. In October another photograph revealed a scaphoid almost normal in shape and density, and in which the natural architecture of the bone is reappearing.

Course of Case.—The possibility of fracture was considered and rejected—the appearances were plainly those of a caries. Examination did not reveal any signs of a developed tuberculous lesion in any other part of the body, but, considering his environment (his father definitely tuberculous, his mother probably also affected), it is not surprising that the boy has since developed undoubted pulmonary tuberculosis.

The alleged injury occurred in December, 1919, and the first skiagram was taken early in February, 1920, after which the foot was fixed in plaster-of-Paris. Open-air treatment was carried out, and the foot kept at rest by re-applications of plaster until September, 1920; the arch of the foot was then found to be weakened; there was a slight degree of flat-foot but no thickening of the scaphoid, or around it, could be made out. By the aid of massage, exercises, rest, and raising of the inner side of the sole of his right boot, complete functional recovery followed by the end of the year.

Remarks.

In reviewing the cases recorded in the literature it is certain that no real causa causans emerges from a theory of "dystrophy" or "delay in ossification" later "stimulated to osteogenesis by trauma." Indeed, a history of trauma could probably be obtained in every case from parents of average intelligence and memory, by careful and persistent investigation, especially if the period inquired into is allowed to stretch as far back as two years before the detection of the disease, and to include injury of any degree of severity.

The conception of the disease awakened by the case I have described is that in a child the subject of a latent mild tuberculous infection there is lighted up (possibly by an injury of moderate severity) a smouldering tuberculosis of the scaphoid bone of the foot, the bone which, being the keystone of the arch, is most subject to strains, stresses, and blows. The early stage, evidenced by a rarefying osteitis, gives rise to such trifling clinical signs that no complaint is made, no X ray examination carried out (unless it be done fortuitously as in Abrahamsen's case[20]), and the disease escapes recognition. Should the disease progress and spread to neighbouring bones the case is diagnosed as a frank tuberculosis of the tarsal bones. But should resolution occur and a reparative sclerosis take place, either no diagnosis other than "sprain" or incipient flat-foot is made, or an X ray examination is made, and the condition found is called Köhler's disease. It is natural then that recovery should "always occur" since the disease is already recovering when detected.

My case is a border-line case, in which actual necrosis to a very limited extent had occurred, but in which the battle had really been won, and which had become, five months after the first observation, a typical case of ordinary Köhler's disease. In every case hitherto recorded the pathology has been deduced from probabilities. This appears to be the first instance of a definite linking-up of the condition with a known disease.

SYMPHYSIOTOMY, CRANIOTOMY, AND CÆSAREAN SECTION.*

By A. E. CHISHOLM, F.R.C.S. Edin.,
ASSISTANT GYNÆCOLOGIST AND OBSTETRICIAN, ROYAL INFIRMARY, DUNDEE.

A study of the case records in the Dundee Royal Infirmary Maternity Department from 1901 to the end of 1922 has brought various points of interest into view.

Symphysiotomy.

During the period 1901 to 1922 symphysiotomy was performed 12 times. The usual indication was contracted pelvis. It may be taken for granted that no one would have recourse to this operation without first having given forceps a fair trial, not to mention Walcher's position, at least in many cases. In one case in this series a brow presentation was given as the indication. Obviously symphysiotomy is of no avail except in mild degrees of disparity between fœtal head and pelvic brim.

The increase in measurement available with an interval between the pubic bones of 6 cm. ($2\frac{2}{5}$ in.) is not very great at the brim, but is of considerably more value, according to Munro Kerr, at the outlet between the ischial tuberosities. The estimated increase at the brim with a separation of 6 cm. is as follows: Antero-posterior diameter, 1 cm. ($\frac{2}{5}$ in.); oblique diameter, 1·5 cm. ($\frac{3}{5}$ in.); transverse diameter, 2 cm. ($\frac{4}{5}$ in.).

Dangers of Symphysiotomy.

The operation is not to be undertaken lightly, for it has its dangers. There is quite a definite maternal death-rate and, apart from loss of life, there are various morbid conditions which may affect the mother. The chief danger is sepsis, and this may go so far as to cause sloughing of part at least of the vaginal wall. Cystitis may also develop, and one must not forget the possibility of injury to the sacro-iliac joints. There is also a fœtal mortality associated with this procedure. It is possible that this might be somewhat reduced if the need for symphysiotomy were recognised sufficiently early, for, no doubt, too strenuous efforts to extract the child with forceps may in many cases turn the scale in the wrong direction and lead to the death of the child.

Symphysiotomy is an operation of limited value and should only be performed under good conditions and if proper after-care is available.

Craniotomy.

With increased antenatal care one would hav expected a distinct drop in the number of craniotom cases, but in the period specified the largest numbe was done in 1921. It is important that antenata care should extend to all private patients as well a to hospital ones. If the private case develops int an emergency (in the private house), the chance of happy issue is less than in the case of a hospita patient unless, as is only occasionally the case, th patient can be removed to a nursing home. As rule, by the time the emergency has arisen, it woul be inadvisable to remove the patient. So the bes thing must be done under inconvenient circumstance and that may mean craniotomy.

In every private and hospital case the ideal is tha the pelvic measurements should be known we beforehand, as also the position and presentation the child, the relation in size of the presenting pa to the pelvic brim, and the state of the urine. this were done as a routine, and if preventive measur were carried out, there would be fewer bad results t both mother and child. Craniotomy is, at best, revolting operation, especially if carried out on th living child. Any operation involving a death-rat of 100 per cent. to the child cannot be an ideal an can only be recommended as the best thing to d under bad circumstances.

At the end of 1922 there was a leading article i The Lancet on Justifiable Fœticide,[1] which wa commented on by (presumably) a Roman Catholi doctor[2]; what the latter said is worth recording, f no doubt most medical men are aware that th destruction of the living child in utero is strictl against the dictates of the Roman Catholic Churc I quote from the doctor's letter: "The teaching the Church with regard to craniotomy is quite clea and definite, it is not permissible under any circum stances." Then there is the order given in Lati He goes on: "This decision was given at Rom August 19th, 1888, and repeated with the pap approbation on July 24th, 1895."

That is all very well, and I do not wish to start controversial argument here on this decision. Bu what I wish to point out is that apparently th authorities of the Roman Catholic Church do n recognise that in allowing the mother to die b neglect of a craniotomy they are still not saving th child, for a dead mother, in these circumstance would mean a dead unborn child. There would th be the certainty of two deaths as against one. Althoug most of us, no doubt, do not agree with a strict ord against craniotomy on the living child, yet we mu all be at one in holding that such a procedure shoul be avoided if it is at all possible and consonant wit the safety of the mother.

There are substitutes—namely, induction of labo and Cæsarean section, not to mention symphysiotom or pubiotomy—under certain circumstances. Prop antenatal care will give the best chance for callin these substitutes into play. Of the cases of cran otomy in this series by far the commonest indicatio was contracted pelvis. There were three cases which hydrocephalus was the indication, and in few cases the operation was performed for vario other conditions. In three of the cases the afte coming head was perforated. From a study of th case-sheets it would appear that nearly all, if n actually all, of the children were already dead befo craniotomy was done, forceps having been found t be ineffectual.

This series shows that there is a real danger death or of morbidity to the mothers. With muc interference there is a particular liability to sept invasion and the patient, too, may become worn o and collapsed. In two cases rupture of the uterus reported.

Perhaps the three chief morbid results, apart fro death, which may follow craniotomy are: 1. Seps from much interference, involving the uterine cavit

---

* Based on a paper read before the Forfarshire Medical Association, in which the actual statistics were given.

[1] The Lancet, 1922, ii., 1182.

[2] Ibid., 1358.

. Septic infection of tears, chiefly of the vagina, due o laceration by sharp pieces of the broken-up fœtal kull. 3. Fistulæ—vesico-vaginal or recto-vaginal—robably from injury with subsequent ulceration hrough to bladder or rectum, rather than from direct aceration right through to one or other cavity at he time of extraction.

CÆSAREAN SECTION.

The cases of Cæsarean section, as would be expected, ave increased in numbers as the years have gone by, he greatest number being recorded in 1922. It is o be expected that the yearly number of these cases vill increase, within limits, for some time to come, ainly because of increasing antenatal care and nticipation of troublesome complications. On the ther hand, it is quite reasonable to suggest that cases f Cæsarean section may be limited in number by nduction of premature labour in selected cases. But Iunro Kerr would seem not to agree with such a tatement, for he says: "Induction of labour does not ome into competition with Cæsarean section, for ery rarely are the results from induction satisfactory the conjugata vera is under 3¼ inches."

One might say that in the mother's interests, in ases of contracted pelvis of varying degree, and if orceps are not likely to avail, induction is the proedure of choice, Cæsarean section the best thing to o if induction is contra-indicated, and craniotomy an nfortunate necessity, as applied to the living child, hen other and better means are not available. In few cases symphysiotomy or pubiotomy may be onsidered. Nevertheless, much may be done by iving plenty of time during labour, combined with Valcher's position in cases of mildly contracted elvis, taking for granted that presentation and osition are normal. It is well in those slow cases to nploy twilight sleep.

Cæsarean section, being a comparatively easy and omewhat spectacular operation, is apt to be abused nd employed unnecessarily.

Of the patients in this series—representing 57 perations—30 were primiparæ and 27 were multiparæ. he patients actually numbered 50, as two were perated on three times and three were operated on vice. In addition, one patient had her second æsarean section performed in the Dundee Royal nfirmary, the first having been done in America.

Cæsarean section is not without its dangers to the others, and certain morbid sequelæ, or even death, ay result. This must be taken into account in eciding between this and some other procedure. lso there is quite a definite fœtal mortality, so that a few instances the objective may be at least partly st on this account. A few cases may be recorded y way of indicating the worth of the operation when operly applied:—

CASE 1.—First child, premature, died in 29 hours; second ild, symphysiotomy, died; third child, Cæsarean section, ive and mature.

CASE 2.—Three children, craniotomy each time; fourth ild, Cæsarean section, alive and mature.

CASE 3.—First and second children, instruments, stillborn; ird child, Cæsarean section, alive and mature.

CASE 4.—First child, instruments, stillborn; second child, esarean section, stillborn; third child, Cæsarean section, ve and mature; fourth child, Cæsarean section, alive and ature.

The indications in the present series (totalling 57) ere:—

Contracted pelvis	51
Contracted pelvis and malposition ..	1
Carcinoma of rectum	1
Placenta prævia	2
Reason not stated	2

As the operation results have improved, so have e indications increased, but discrimination and rbearance are required lest it be undertaken rashly d without necessity. For there are not only mediate dangers, but late ones, such as rupture of e uterine scar at a subsequent pregnancy.

Indications.

1. *Contracted pelvis.*—This is the commonest indication. This may be actual or relative, for a postmature child passing through a normal pelvis will create the same problem as an ordinarily mature child passing through a narrow pelvis. Pelvic measurements taken in advance are of great value, but, as it is said, the best pelvimeter is the fœtal head. The relationship can usually be fairly accurately estimated by abdominal or bimanual palpation. Thus a decision may be come to either for or against the operation in any given case. Roughly speaking, a conjugata vera of 3¼ inches or less is likely to lead one to consider the advisability of performing Cæsarean section, unless the child is very small.

If the child be dead, craniotomy would be the operation of choice, unless the pelvic contraction or deformity is too great for that to be justified.

2. *Tumours.*—These are chiefly fibroids and ovarian tumours. As pregnancy advances, or in the early stages of labour, the tumour may rise out of the pelvis and thus cease to be a cause of obstruction. If it remains in the pelvis Cæsarean section is indicated, for it is dangerous to both mother and child to try to drag the child past the obstruction. A thin-walled cyst might rupture during the process and thus remove the trouble. Under proper circumstances it may be deemed wise to remove a tumour, when recognised, during pregnancy, deliberately running the risk of inducing premature labour by such interference. More often it would be indicated to do a Cæsarean section at term and deal with the tumour at the same time. Other tumours need not be specified.

3. *Eclampsia.*—The indication for Cæsarean section in this condition is not very great. The child is often dead in any case, and the results to the mother do not greatly encourage recourse to this method of treatment. Success might possibly be more frequently ascribed to Cæsarean section if it were carried out in the early stages of the eclampsia. At the British Congress of Obstetrics and Gynæcology held in Liverpool in June, 1922, Cæsarean section did not take a very high place in the treatment of eclampsia. The cases were divided into mild (M.) and severe (S.).

Cæsarean section may be required in cases of eclampsia for some other reason, quite apart from the eclampsia itself—e.g., contracted pelvis.

4. *Placenta Prævia.*—Lawson Tait recommended Cæsarean section for this condition in 1898. In selected cases this may be the operation of choice, under suitable conditions, as one would not expect the maternal death-rate to be raised, and certainly the fœtal death-rate should be lowered very considerably. But one would deem it wise to operate very early in labour, or just before its onset, before the placental circulation has become seriously embarrassed or cut off, and before much vaginal examining has been done, involving the greater risk of sepsis. It would seem unwise to advocate the operation in merely marginal cases and also in cases in which there has been so much bleeding with, presumably, wide separation of the placenta, that the child must almost certainly be dead.

5. *Accidental Hæmorrhage.*—Cæsarean section would rarely if ever be done for this complication in mild cases, and in severe cases the child would usually be dead. Hence the indication would be to save the mother, if it is considered that bleeding is still going on to a dangerous extent, and if she cannot be delivered quickly enough in the normal way, or if it is considered that she might stand Cæsarean section

but would very likely succumb to the prolonged strain of labour.

Other Indications.—Other possible indications, which may be briefly dismissed, are as follows :—

(*a*) A uterus which has had one or other fixation operation performed on it which will limit its power of expansion in the proper form and is thus in danger of rupturing or of becoming impacted.

(*b*) The operation might be justifiable in a very few cases of prolapse of the cord if the child were still actively alive and if the cord could not be retained in the uterus.

(*c*) It might be done occasionally in certain cases of malpresentation or malformation of the fœtus, and in certain cases of abnormality of the maternal passages—e.g., retraction ring, rigid os, bone tumour, and so forth.

(*d*) Some diseases might also be considered as indications for the operation, such as certain forms of cardiac disease.

In the present series there were eight re-operation cases. In one of these (third Cæsarean section) the uterine wall was said to be thin from old scars, and in another case (second Cæsarean section) the lower part of the old scar was found to have given way after the placenta had been removed. It is no uncommon experience, however, to be unable to find a previous scar at the time of a subsequent operation.

Eardley Holland gives the frequency of rupture of Cæsarean section scars in subsequent pregnancies as 4 per cent., the cause being imperfect healing leading to a thin scar which stretches during pregnancy and ruptures on account of increased intra-uterine pressure either during pregnancy or during labour, or, it may be, from an accidental cause.

The chief cause of imperfect healing is, no doubt, infection and possibly the suture material may have something to do with it. Holland seems to be against catgut as a suture material, stating that there is two-and-a-half times the liability to rupture subsequently if it has been employed. He rather favours silkworm gut, although this is a material which, for other purposes, is rarely if ever employed for buried sutures. Any kind of suture material—catgut, silk, silkworm gut—may give excellent results if sepsis is avoided and if the whole thickness of the uterine wall is brought into accurate apposition.

Of the 57 cases, 52 were in labour, 1 was not, and in 4 cases this point was not indicated. One advantage of the patient being in labour when the operation is carried out is that drainage downwards may be more effective, as the os will be definitely open. Also it more or less ensures, as nearly as can be, the full maturity of the child. It is said that the uterus will contract better afterwards if labour is in progress, but the stimulus of the operative interference is quite sufficient for this purpose in the case of a normal uterus. It has been suggested, too, that in primiparæ there may be more tendency to trouble from after-pains, if the operation has been performed before the onset of labour, on account of the retention of discharges in the cavity of the uterus.

But a possible disadvantage in waiting till labour comes on is that arrangements may have to be made in a hurry and results may be prejudiced where such an emergency arises in private practice, necessitating transport to a nursing home at a time when the patient is not very fit for it. It is probably better in a private case, if Cæsarean section has been decided on, to do it at a given date, as nearly as possible just before labour is due to start, or to have the patient in a home in good time and let her wait till labour has just started before operating. It must not be forgotten that there is a distinct danger of sepsis with tragic results if a Cæsarean section is done on a patient who has been much examined or on whom attempts at delivery per vaginam have been unsuccessfully made. Many operators would rather do a craniotomy under such circumstances. The maternal death-rate in Cæsarean section is by no means negligible, death being due to such causes as sepsis and pulmonary embolism.

Sterilisation of patients is a matter for judgmen in each case. Sometimes there may be little doub in coming to a decision. For example, the risk o sepsis may be so great from previous interference tha even a hysterectomy may be considered necessary Again, a uterus may be so damaged by previou Cæsarean sections that it may be advisable to sterilis the patient. But nowadays it is rarely right t sterilise after the first Cæsarean section or at a subse quent one if no living child has been born and ha survived, unless the uterine condition is such as t forbid the risk of another pregnancy.

I am indebted to Dr. R. C. Buist and Prof. J. A Kynoch for permission to use their case records.

TUBERCULOSIS OF THE PERICARDIUM

BY W. E. WALLER, M.D. OXF., M.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, CROOKSBURY SANATORIUM.

TUBERCULOSIS of the pericardium is not of ver common occurrence, and many authors deny alto gether the existence of primary pericardial tuber culosis. Hedblom[1] has recently collected from th literature eight cases in which the pericardium wa considered to be the primary seat of the disease F. T. Roberts[2] points out the rarity of miliary tuber culosis of the serous pericardium as compared wit other serous membranes, and states that most of th cases are chronic, and secondary to tuberculosis else where, especially of the lungs and bronchial glands He emphasises the fact that, even in such cases wher pericarditis actually exists, it is sometimes difficul or impossible to prove, either histologically o bacteriologically, its tuberculous origin.

Table I. is an analysis of 83 cases of pericarditi which were admitted into the medical wards o St. George's Hospital between the years 1911 and 192 This number excludes cases of hydropericardium du to back pressure.

TABLE I.—*Analysis of 83 Cases of Pericarditis.*

Type.	No. of cases.	Male.	Female.	Average age.	Per-centage
Rheumatic ..	54	28	26	15·7	65·5
Renal	13	7	6	36·9	15·7
Pneumonic ..	9	7	2	17·3	10·9
Septic	4	2	2	28·7	4·3
Tuberculous ..	3	1	2	20·3	3·6

TABLE II.—*Details of the Three "Tuberculous" Case in Table I.*

Case.	Sex.	Age.	Pericardium.	Tuberculosis elsewhere.	Remarks.
1	M	8	Miliary T.B. of serous coat with effusion.	Caseating tuberculosis of mediastinal glands. Miliary T.B. lungs, pleuræ, and generalised.	—
2	F	50	Chronic adhesive pericarditis. Serous coat studded with tubercles.	Bilateral apical pulmonary tubercle with bilateral pleural effusions.	Old histor pleurisy with effusio
3	F	3	Acute sero-fibrinous pericarditis, with 3 oz. of effusion. Early endocarditis of mitral valve.	Caseating tuberculosis of infratracheal glands. Scattered T.B. in lungs, liver, and elsewhere.	Pericarditi possibl rheumatic i origin.

Table II. gives details of the three cases, 3·6 pe cent. of the total, which were regarded as bein tuberculous in origin. It will be noted that in th first two cases there was miliary tuberculosis of th erous coat, but evidence pointed to the spread of his process from elsewhere. In the third case, the uberculous origin of the process was doubtful.

[1] Hedblom: Surgical Clinics of North America, Oct. 21st, 1921
[2] Roberts, F. T.: Allbutt and Rolleston's System of Medicine

In view of the preceding remarks, the following ase, which is not included in the above series, is of nterest.

A girl, aged 6, admitted into St. George's Hospital on an. 22nd, 1922. According to her mother, she came of a ealthy stock, had suffered from influenza, possibly accom-anied by left-sided pneumonia, in 1919, but had been erfectly well ever since, until Dec. 28th, 1921. On that lay she was feverish, complained of sore throat and rather evere epigastric pain, unaccompanied by vomiting, which assed off after 24 hours. Subsequently there was no eturn of pain, nor was there undue shortness of breath, ut she remained languid, with lack of appetite, and desire o rest. On Jan. 15th there was rather severe cough, she ppeared very ill, and was feverish at night.

Condition on Admission.—She appeared well nourished, he tongue was coated, the fauces were not injected, and the onsils not large. The temperature was 100·8° F., pulse 140, nd respirations 44. The apex beat could be felt with ifficulty in the normal position; there was no apparent ncrease in the cardiac dullness, though præcordial percus-ion was painful. Heart sounds, though distant, appeared ot abnormal, and no friction or murmurs were present. omparative dullness, with very poor air entry, at both bases.

Course of Case.—Subsequent to admission the tempera-ure was erratic, tending to rise to 100° at times, and some-mes normal for 24 hours, but the pulse and respiration-ate remained high, the degree of illness present greatly xceeding the signs of organic disease. On the 24th a kiagram of chest suggested the presence of fluid at both ases. The pericardial shadow was not unduly large, and howed no truncation of the cardio-hepatic angle. On the 8th the left base was explored, and 150 c.cm. of clear terile fluid was removed, the small lymphocyte being the redominant cell present, though polymorphonuclear and ndothelial cells were also numerous. The course of the isease was unaffected by this procedure, and death occurred ather suddenly and unexpectedly on the 28th.

Necropsy.—Both pleuræ contained 8 oz. of clear fluid, nd there were recent adhesions at both bases. Both he parietal and visceral pleuræ were free from obvious ubercle. The lungs were intensely engorged, with collapse t the bases, but no tubercles were present either on the urface or on section. The pericardium was fairly firmly dherent to the back of the sternum and costal cartilages y rather fleshy pink adhesions, which appeared to consist artly of fibrous tissue and partly of a substance resembling ranulation tissue. There was severe chronic proliferative ericarditis, both fibrous and serous coats being much hickened and laminated, varying in places from ¼ to ½ inch thickness, especially at the apex. The inner surface of he pericardium and epicardium was covered by a thick pile" of granulations, to which were adherent peduncu-ted masses of partially organised lymph, these masses eing remarkably uniform in size, and somewhat resembling melon-seed bodies." Some of these masses formed dhesions between the layers, imperfectly dividing the vity into loculi, which contained a little turbid fluid. No cognisable tubercles were present. The heart muscle, on ction, was firm and good, there being no mural tubercles. he valves were normal. The peritoneum showed severe dema, and contained ten oz. of fluid similar to that om the pleura, but showed no tubercle. The liver was rd, and showed early "nutmeg" change. Scattered over s capsule were a few tubercles of the size of a pin's head, me of them showing commencing caseation, whilst, on ction, a few similar tubercles were scattered throughout. he spleen was hard, firm, and tough on section. On its terior margin was a caseating tuberculous focus of the size a pea, whilst, on section, there were scattered foci re-mbling those of the liver. The kidneys were normal d free from tubercle, and there was no tuberculosis else-here. The lymphatic glands showed no obvious abnor-ality, whilst the infra-tracheal glands, believed by many be the focus from which tuberculosis spreads to the ricardium, were very small and insignificant.

Microscopically, several mediastinal lymph glands were amined, and in all there was marked venous engorgement, ough no tubercle was detected. Sections stained by ehl-Neelsen's method showed no tubercle bacilli. Sections om the pericardium showed great increase in thickness of e fibrous coat, the tissues being laminated and very llular, the spaces between the laminæ being richly infil-ated with round cells, in some places these being so assed as to present the appearance of lymphoid tissue. he serous coat was not recognisable, but was replaced by pical granulation tissue, with loops of new and well-rmed capillary vessels reaching to the surface. No giant-ll systems were recognisable, and no tubercle bacilli were present in the granulation tissue. Sections through the lymph masses showed thick fibrin, with many degenerated white cells and masses of their nuclear debris.

The interest in this case lies in the relation of the pericarditis to the tuberculous lesions, and further emphasises the care with which these cases should be investigated. It was unfortunate that, in this case, no inoculation tests were undertaken with material from the pericardium. The pleural and peritoneal exudates probably resulted from back pressure, a supposition supported not only by the hepatic condition, but also by the remarkable degree of œdema of the peritoneum. If it is assumed that the pericarditis was tuberculous in origin, in view of its chronic proliferative nature it would appear to have been the primary seat of the disease. If, on the other hand, the pericarditis was due to other causes, as from a tonsillar organism, it is difficult to explain the focus from which the miliary tubercles in the spleen and liver originated.

Clinical and Laboratory Notes.

NOTE ON "BAKERS' ECZEMA."

By Arnold Rowsby Tankard, F.I.C.,
PUBLIC ANALYST FOR THE CITY OF HULL.

In January, 1913, a journeyman baker called to show me his forearms, which almost up to the elbows presented a definite eczematous condition. This "eczema" became at times so severe that it was difficult for the bakers to continue their employment. It appeared that several different kinds of wheat-flour were used for bread-making at the bakery in question, but the bakers had noticed that it was only with one brand of flour that the "eczema" made its appearance. Several bakers were affected by irritation of the hands and arms, and later with "eczema," when this particular flour was being worked up.

As a sample of the flour revealed no abnormality of composition when subjected to the usual methods of chemical analysis, I made a careful study of the patent literature dealing with the addition of so-called "improvers" to flour, and from a formidable list of chemicals which have been suggested for this purpose several were chosen for investigation. Without going into further detail, it may be stated that one of the substances considered likely to cause trouble when brought into contact with delicate skin surfaces was potassium persulphate, owing to its known acid formation when moistened with water:—

$$\underset{\text{Potassium persulphate.}}{2\ K_2S_2O_8} + 2\ H_2O = \underset{\text{Potassium acid sulphate.}}{4\ KHSO_4} + O_2.$$

Investigation showed that the suspected flour contained this chemical to an appreciable extent, although the amount was not sufficient to cause any noticeable increase of the normal content of mineral matter present in flour of that grade.

The information given to me by the baker made it quite clear that this flour containing persulphates was the only one causing any trouble, and it was stated that the men were declining to work this particular flour owing to its action on the skin. Later, samples of this flour obtained from the miller on delivery to a local grocer were examined and found to contain potassium persulphate, and action was then taken under the Sale of Food and Drugs Acts against the actual miller for selling flour not of the nature, substance, and quality demanded, by reason of the fact that it contained a foreign mineral substance, potassium persulphate, to the extent of 6·3 parts per 100,000. The case was heard before the stipendiary magistrate at Hull in 1913, the hearing occupying four days, but after the expenditure of a considerable sum of public money, with the sole idea of protecting the public from the undeclared addition of foreign substances to flour—substances which may or may not be harmful, either in themselves or by reason of impurities introduced with them—the case was dismissed, each side paying its own costs. The opinion of the Local Government Board at that period was that the law as it stood was sufficiently strong to prevent such additions, but this case showed that such practices could not be effectually stopped by action under the Sale of Food and Drugs Acts; and although a Bill was introduced some years ago into Parliament making provision for such cases, it was not proceeded with, and the present position remains quite unsatisfactory. It had been hoped by many food chemists and others that the Ministry of Health would before now have taken steps to prevent such additions to flour, but unfortunately nothing has been done in this direction.

The Lancet, in an annotation in its issue of July 7th[1] last, cites a case of sensitisation to wheat-flour which produced chronic eczema in a woman; and O. de Jong, in a recent paper on "A Suggested Ætiology of Bakers' Dermatitis,"[2] accounts for such cases by the presence of salt in the yeast mixture and in the dough handled by bakers. If this explanation is sound, then a similar condition amongst bakers should have been common for many years. This, however, is contrary to my information. It would be interesting to know whether these skin affections among bakery workers occurred with any frequency prior to 1911, the date of the first patent for the use of persulphates as "flour-improvers," and whether the flour handled by de Jong's patients contained this chemical. A flour may appear normal in every respect and yet contain persulphates, for which a specific search must be made. In Hull, at least, common salt without persulphate in the flour caused no such trouble to the bakers in the particular bakery where my informant was engaged.

The cases of "bakers' eczema" which have occurred in this city, so far as they are known to me, have always resulted from the handling of "wetted" flour—that is to say, the dough mixture, which to a greater or less extent comes into contact with the arms during the process of hand-mixing. This is precisely what one would expect in the case of a substance like potassium persulphate, which decomposes fairly rapidly under these conditions, with formation of potassium acid sulphate, as stated. I have no doubt that, so far as the cases brought to my notice in Hull are concerned, the cause was the presence of potassium persulphate in the flour, since (1) only when flour containing potassium persulphate was being used was any skin trouble evident, and then only when the flour was handled in a moistened state; and (2) when this flour was not used, but flour free from potassium persulphate substituted, with salt, yeast, &c., as usual, no trouble was experienced, and the eczematous condition of the skin of the affected workers gradually disappeared.

HERNIA OF THE VERMIFORM APPENDIX THROUGH HESSELBACH'S TRIANGLE.

By Margaret W. Snodgrass, M.B., B.Ch. Belf.,
HOUSE SURGEON, DORSET COUNTY HOSPITAL, DORCHESTER.

The following case of a hernia of the appendix merits record:—

A male, aged 70, was admitted to this hospital under the care of Mr. W. B. Cosens with the diagnosis of right strangulated hernia. He had a previous history of left inguinal hernia for 20 years, with no history of any trouble on the right side. On examination a tumour, the size of a small tangerine orange, was found occupying the region just above the inner third of the right Poupart's ligament; the mass was tender, with slight lateral movement, and pain was referred to the umbilicus. The early symptoms of strangulation had been present for 24 hours.

Operation revealed the appendix in a mass of omental adhesions passing through Hesselbach's triangle; the inguinal canal was normal.

It would be interesting to know if there has been any case reported of the appendix *alone* finding its way through this anatomical region.

Reviews and Notices of Books.

The Older Universities of England: Oxfor and Cambridge.

By Albert Mansbridge, Hon. M.A. Oxon
London: Longmans, Green and Co. 192
Pp. 296. 7*s.* 6*d.*

This remarkable book is written by one who wa not educated at either university, but who in som mysterious way understands the university spirit an is quite alive to the influence which Oxford an Cambridge should, and as a rule do, exercise. Ther are still some who sigh for the placid days befor 1850 when the Commission was instituted which s vexed the soul of Archdeacon Grantly and man another, when the Hebdomadal Council was al powerful and when Newman in the pulpit of th University Church was making young men to realis the fact that they had spiritual duties to perform.

It was between 1870 and 1880 that both universities awoke to the fact that what is now calle "social service" was a duty which the rich owed t the poor, and a university sermon by Pusey preache in 1875 laid solemn stress upon this:—

> "Many of you, my sons, are provided with superfluities You have not to stint yourselves as to the pleasures of you age. Day by day, I suppose, passes with all convenience of life or amusement, or some self-indulgences, which thoug not directly sinful, are rather injurious. If our Lord wa to come now, in how many do you think that you coul tell Him that you had fed Him, clothed Him, supplied Hi when sick? Some, I fear, could not say that they ha bestowed as much upon Christ as upon their dogs."

But though individual members of the university as is shown by the foundation of university settlements, were not deaf to the call of those who ha never enjoyed a university career, practically nothin was done to make the way of the poor scholar easier One of the evils wrought by the Commission of 185 was the abolition of the "poverty clauses" and th substitution of "merit" which meant ability to pas examinations, an abolition which Dean Burgo deplored (v., p. 109). So, says Mr. Mansbridge on th same page, "the most difficult time for the poo scholar to get to Oxford or Cambridge was from 185 to 1904." But although Mr. Mansbridge is all fo giving working men and women every facility of acces to university life and teaching he is no iconoclast He recognises that there is in university life a atmosphere or environment which makes men lov knowledge for its own sake and not for that of utility

> "Directly Oxford and Cambridge seek to conform themselves to modern needs, to justify themselves to the Philistine outside—however excellent in other ways such Philistine may be—they may do more work which can be recorded i elaborate tomes, they may send out more young men t perform the tasks of the city and the factory, but they wil lose that ineffable charm, that pulsating power, tha mysterious influence which calls forth the veneration o men in other universities and in other lands,"

and he quotes with approval the remark of a Maste of Corpus, Cambridge: "Cambridge is not primaril a place of learning or a place of examination. It i a place where you live three years."

Mr. John Mansbridge's illustrations are worthy o the book, especially the reproductions from penci sketches; his drawings in Loggan's style are not s successful and the view of Magdalen is really bad. We have noticed a few slips in the text—e.g., on p. 217 Tennyson's date is given as 1809–1902, instead of 1892, and in the index Dr. Routh is entered a Master of Magdalen instead of President. But unti we read the book we could not have believed that an outsider could so have caught the spirit of a university or have written so sympathetically. Mr. Albert Mansbridge was nominated as one of the Commissioners of 1919–22 and no better selection could have been made. Every university man and every man who seeks to be a university man should read the book.

ONTRACEPTION (BIRTH CONTROL): ITS THEORY, HISTORY, AND PRACTICE.

A Manual for the Medical and Legal Professions. By MARIE CARMICHAEL STOPES, D.Sc. Lond., Ph.D. Munich, Fellow of University College, London. London: John Bale, Sons and Danielsson. 1923. Pp. 417. 12*s.* 6*d.*

Dr. Stopes tells us in her preface that this book presents the arduous toil of four years ; in it she has ideavoured to set out clearly all that is valuable of vailable knowledge on contraception, hoping thus to ive cleared the way for the initiation of deeper searches as well as for the determination of the best actical means of contraception to suit specific cases. the 14 chapters which follow Dr. Stopes sets out th precision and no little literary grace the problem contraception as she sees it, the indications for use, a description of contr aceptives desirable and idesirable, answers to some objections which have en raised, the history of its practice in this and her countries, and a note on the need for instruction medical schools. Finally, she describes the daily actice of the birth control clinic inaugurated by her Holloway. The parents visiting this clinic are, . Stopes tells us, made to feel that they come not to lk about disease, nor to be subjected to operation, t "to discuss in an inspiring way in attractive rroundings one of the greatest and one of the most cially vital questions which arise in their lives." No ter of introduction is required, no fees are taken. ly mother or father, who desires to do so, can walk o the clinic at any time. The simple and decent ocedure is described, and Dr. Stopes adds that few men require a second instruction, although the endly atmosphere of the clinic and the sympathy of nurse encourage them to come again if difficulty uld arise. Dr. Stopes concludes her book by scribing the practice of contraception as "in many ys the connecting link between health and disease." e prime object of the medical profession being the alth of the community, she regards a full knowledge contraception as one of the doctor's most useful juncts, for "when used by diseased persons contracep- n becomes the great preventive measure to arrest the ead of disease and degeneracy through the nation." find some essential truth in this declaration along h some of the exaggeration which is characteristic the prophet who believes that a message is entrusted him or her alone. Just as it is futile to try to mote the general health of the community without intimate study of the early beginnings of disease the deviations from normal function, so no doubt practice of normal healthy sex relations cannot be on a firm footing without close study.

Much of the evidence contained in the book is te unobtainable elsewhere, for the author has n the confidante of hosts of marital difficulties. re it not in fact for the opening pages of the volume medical reader would feel inclined to accept it as ext-book on a specialty in which the author has de herself proficient. But a feeling of doubt and plexity is engendered by the extraordinary number ntroductions from distinguished medical men and nen which precede the opening chapter. Sir liam Bayliss first sets out the two chief arguments avour of birth control, the one being the relief of mother from the results of frequently repeated gnancies, the other, like unto it, being the possi- ty of a normal and beautiful married love—a sibility which, he adds, Dr. Stopes has had the our of bringing out into a clear light. The records t at the mother's clinic will, he hopes, in time lead he accumulation of valuable information so that may be able presently to recommend the best hod in any given case and to issue warning against use of those likely to be injurious. Sir James Barr roaches the subject from the racial point of view laughs to scorn the argument that if young women w the use of contraceptives they would lose any ality which they now possess. The sentimental f contained in prurient novels should, he thinks, be replaced by genuine information. The innocence of ignorance is not worth preserving. Dr. Christopher Rolleston testifies to the value of Dr. Stopes's book to the medical officer of the smaller English counties who, unlike his brother in larger cities, comes into intimate clinical contact with his neighbours from their birth (or before) to their death. Dr. Jane Hawthorne adds a brief benediction and a medical barrister-at-law, who signs himself "Obscurus," justly compliments the author on having given references for every quotation she has made, but does her disservice in stating that, had she been on the Medical Register, she might well have been cited before the General Medical Council to answer for her views. Whatever disciplinary terrors the Council may wield, it certainly never questions the right of the thinking men or women whom it registers to hold what views are dictated to them by knowledge or conscience.

NEUROLOGICAL DIAGNOSIS.

Kompendium der topischen Gehirn- und Rückenmarksdiagnostik. By ROBERT BING, Professor in the University of Basel. Fifth enlarged and corrected edition. Berlin and Vienna: Urban and Schwarzenberg. 1922. With 102 illustrations, partly in colour. Pp. 242. M.450.

Dr. Robert Bing's book on neurological diagnosis is well known in this country and has been frequently reviewed in these columns. The latest edition contains various additions and corrections which do not add materially to its length. There are some new diagrams and illustrations, the former characterised by the same simplicity and clearness that have been features of Dr. Bing's diagrams from the outset. Eschewing controversy and speculation, the author confines himself, with singular success, to the anatomy and physiology, normal and pathological, of the nervous system, and if it is impossible for him to avoid some vexed questions—e.g., that of the relation of the corpus striatum to other centres, above and below—his teaching is sufficiently definite to be instructive, even though exception might easily be taken to some of his statements. One or two of the criticisms we offered in a previous review have been met, but there are others which if accepted would, we believe, bring the work even more close to that ideal of neurological doctrine which every teacher desires. The fact that a fifth edition is issued is comment enough on the practical nature of this compendium, which can once more be recommended to all students of the nervous system and its disorders.

TUBERCLE BACILLUS INFECTION AND TUBERCULOSIS IN MAN AND ANIMALS.

By Albert Calmette. Authorised translation by WILLARD B. SOPER, M.D., and GEORGE H. SMITH, Ph.D. Baltimore, U.S.A.: Williams and Wilkins Company. 1923. Pp. 689.

THE original French edition of this valuable book was noticed in THE LANCET (1920, ii., p. 74) on its publication, and though there is little to add to what was then said, it is a pleasure to welcome this authorised English edition. The translators have performed their task admirably, and have added the index which was omitted from the original work, after the regrettable custom of France. They have been ably supported by their publishers and the result is a volume which should be in the library of every student of tuberculosis, whether he works on the clinical side or in the laboratory. Quite apart from the wealth of information it contains, this monograph has a value which it is difficult to overestimate. The author's individuality is stamped on every page, and he has given us not only a brilliant account of the present state of knowledge of tuberculosis, but also a model of what constitutes the best type of scientific work.

HÆMATOLOGY AND HISTOLOGY.

Traité technique d'hématologie, morphologie, histogenèse, histophysiologie, histopathologie. Par J. JOLLY, Directeur du Laboratoire d'Histologie de l'École dés Hautes Etudes au Collège de France. Paris: A. Maloine et Fils. 1923. With 69 figures in the text and one coloured plate. Two vols. Pp. 1130. Fr.70.

THE author holds that all sound biological work must rest upon a basis of morphology and histology, and he has furnished the proof of his doctrine, if any proof is necessary, in this exhaustive treatise. It is essentially a monograph on the structure of the cellular elements of the blood, but Mr. Jolly loses no opportunity of pointing out how function depends on structure, and how the one varies with the other. The book is planned on the broadest possible lines. The first few pages contain instructions how to obtain blood from animals, birds, fishes, and reptiles, and though naturally man is the chief subject of observation, the author never hesitates to refer to lower orders of life when necessary. Though the morphology and the quantitative variations of the cells of the circulating blood, including, we may note, the platelets, are treated of in detail, this aspect of the question forms only a part, and not the greater part, of the book. The wandering cells of the tissues in normal and pathological states are described at length; and there are equally comprehensive chapters dealing with the structure of lymphadenoid tissue, the spleen, the bone-marrow, and the thymus. There are chapters on hæmoglobin, the coagulation of the blood, hæmolysis, and histogenesis. The last chapter on the relations of the blood with the body and with the outside world is not the least valuable. Mr. Jolly has written a truly philosophical treatise on an intensely interesting subject. If we have omitted to mention that there are chapters dealing with the anæmias and the leukæmias it is because these abnormal states are put in their proper place; they exist, and they are faithfully dealt with, but for Mr. Jolly the study of the blood means much more than it does to most medical authors. The illustrations are adequate, and the format of these paper-bound volumes leaves nothing to be desired.

VENTILATION.

The Ventilation of Public Buildings. By ROBERT BOYLE. London: Robert Boyle and Son. 1923. Pp. 51. 6*s*.

THIS very short book contains a compilation of statements by various individuals in favour of the natural system of ventilation. There is little general information on ventilation, the object apparently being to advertise the fact that the consensus of opinion in this country is in favour of the natural system of ventilation and opposed to all artificial systems. The book is illustrated.

Calculations in Heating and Ventilation. By G. S. COLEMAN, D.Sc., Assoc.M.Inst.C.E., Director of the Department of Municipal and Sanitary Engineering in the Municipal College of Technology, Manchester. London: Longmans, Green and Co. 1923. Pp. 249. 15*s*.

THE main object of this excellent book is to provide working examples for students taking the second and third years in the advanced course in heating and ventilating engineering at the Municipal College of Technology, Manchester. The author claims no originality and expresses his debt to the more comprehensive and standard works. In addition to the chapters on calculations, there are chapters on mechanics and physics, conveniently placed for reference, and a means of saving the student much time. The book contains instructive illustrations, tables, and charts, and also much technical information in a readable form. More space could have been allotted with advantage to the kata-thermometer, an instrument which has now proved its value in many countries.

DELAFIELD AND PRUDDEN'S TEXT-BOOK PATHOLOGY.

Twelfth edition. Revised by FRANCES CART WOOD, M.D., Director of the Pathological Depar ment, St. Luke's Hospital, New York; Direct of the Institute of Cancer Research, Columb University, New York. New York: William Wo and Co. 1922. Pp. 1354. 63*s*.

THE twelfth edition of this excellent text-bo differs little from the previous one published in 19 though it has been subjected to a careful and detail revision. The sections on the liver and the centr nervous system contain a good deal of new matter a are improved by additional and useful illustration and portions of the section on tumours have been written. By careful pruning the author has succeede in effecting these changes without increasing the si of the book, which remains one of the most satisfacto examples of its kind.

A SURGICAL ATLAS.

Spezielle Chirurgie. Part II. Second edition. B Prof. G. SULTAN. München: J. F. Lehman 1923. Pp. 576. 14*s*. 5*d*.

THIS is a revised edition of a well-known surgic atlas. The illustrations do not differ very much fro those which appeared in the former edition, but th letterpress has been considerably altered. Certa illustrations and descriptions might well have bee omitted, such as Kocher's method for the radical cu of hernia, and possibly, too, the technique of the use Murphy's button, which now is only of historic interest. There are some rare conditions depicte which one very seldom meets. The atlas is a collectio of extremely good pictures which really help th student to visualise disease which he may not have ha an opportunity of seeing.

DISEASES OF SALIVARY GLANDS AND PANCREAS.

Nouveau traité de médecine. Vol. XV. *Gland salivaires, pancréas, et péritoine.* Edited b G. H. ROGER, FERNAND WIDAL, and P. J. TEISSIE Paris: Masson et Cie. 1923. Pp. 568. Fr. 40.

THE fifteenth volume of this System of Medici bears the same signs of scholarship and scrupulo preparation that we have observed in earlier volume Dr. E. Parmentier and Dr. Etienne Charbrol a responsible for the section dealing with the saliva glands and the pancreas. We have been particular impressed by their excellent discussion of the patholo of diabetes. In reading this article on page 8 with its cold and logical exposition of the arguments f and against the pancreatic theory, one feels th enormous importance of the work of F. G. Banti and how sensibly future progress in pathology must b modified by this new knowledge. The problems pancreatitis are no less ably dealt with, this sectio being, like others, enriched by collections of statisti which are of great value. The major portion of th last section of the volume, which deals with diseases the peritoneum, is by Dr. Paul Londe, and is marke by the same scrupulous care. We have no hesitatio in recommending this as an admirable reference wor

JOURNALS.

TROPICAL DISEASES BULLETIN. July, 1923.—A instructive feature of the July number of the *Tropic Diseases Bulletin* is the critical review, by C. M Wenyon, of the bodies in the blood which have, fro time to time, been described as "hæmogregarines of man.—Clayton Lane contributes a number reviews on malaria, while C. M. Wenyon is responsib for the sections dealing with kala-azar, relapsing feve infectious jaundice, and yellow fever.—Novel labora tory methods are summarised by J. D. Thomson, an under the miscellaneous category subjects such a psychoses and rabies are dealt with.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS, H TO O.

WE are requested by the Registrar of the General Medical Council publish the following list of medical practitioners who have not plied to his inquiries as to the accuracy of their addresses. The t includes all untraceable names from H to O in the body of the Medical egister, as it is only this section which has come under review this ar. Anyone who finds his or her name included in this list should mmunicate immediately with the Registrar of the General Medical uncil, 44, Hallam-street, Portland-place, London, W. 1. Since this t was prepared a large number of further inquiries have been sent out, t it would be advisable that in all cases in which a practitioner's me appears in the list a communication should be addressed to the egistrar.

TERNATIONAL UNIFORMITY IN PHARMACOPŒIAL PREPARATIONS.

SOME NEW SUGGESTIONS.

THE problem of an International Pharmacopœia s discussed at the general assembly of the Intertional Pharmaceutical Federation, which met in ndon recently at the same time as the British armaceutical Conference.

The subject is not a new one, and we may recall it already, in 1877, at the Fifth International dical Congress of Geneva, following a report from . Gilles, it was agreed that uniformity both in the menclature and the composition of medicaments s highly desirable. A committee was appointed to dy the subject and to inquire into the matter of universal codex which had been prepared by the ciété de Pharmacie, of Paris. At the next Congress msterdam, 1879) this committee was enlarged, and was decided to accept the French draft as a basis l have it published. The French formulary, wever, passed through many vicissitudes and was ver set in print. In 1881 the Seventh Medical ngress met in London at the same time as the th Pharmaceutical Congress. They had a joint eting, and after a long discussion two committees re appointed, one by each body, to collaborate and pare a restricted formulary that would receive eral approval. The Pharmaceutical Committee blished the result of its labours in 1885 (Sixth ngress, Brussels), but it remained a dead letter.

Once more, at the Moscow Medical Congress of 1897, question was raised and a proposal put forward to l a Government that would give its support to undertaking. During the year following the ussels Academy of Medicine requested the Belgian vernment to convene a representative interional conference for the purpose of standardising ent galenicals. The conference met in 1902 and lded the first practical result in the form of an ernational agreement regulating the strength of ne 40 poisonous preparations. Since then very le advance has been made, but the International armaceutical Federation has recently decided to ew the attempts.

Prof. van Itallie (Leiden), in his presidential ress to the Federation, remarked that the Brussels eement, though an excellent beginning, has become iquated and, like every national pharmacopœia, uires corrections and extension. As President of Pharmacopœia Committee of Netherlands, he fully aware of the large amount of work necessary its revision. He had, therefore, proposed last r that an international secretariat should be rusted with the task of collecting the data needed bringing up to date national pharmacopœias, s promoting uniformity. A committee of chemists, rmacologists, clinicists, and serologists could rwards compile an international pharmacopœia restricted scope, containing only the more import- drugs and their preparations, together with accurate hods of testing. The need for national medicines ıld still exist, but every country would be free to have its own additional formulæ. In most places we find already side by side an official pharmacopœia and a national formulary.

Dr. J. J. Hofman (Secretary of the I.P.F.) stated that the Belgian Government had been requested to bring together a second international conference in order to discuss the institution of a central pharmacopœial secretariat as outlined by Prof. van Itallie. The Belgian Government had not yet signified its acquiescence, and if it should refuse another Government will have to be approached.

A slightly different proposal was put forward by a group of British pharmacists and analysts, who communicated to the Conference a number of monographs dealing with the international standardisation of pharmacopœial preparations. Mr. V. Cofman, B.Sc., in introducing these papers, explained that they had put aside, for the time being, the ambitious aim of an international pharmacopœia. The immediate aim was to attain uniformity in the case of the really important drugs, so that potent preparations which had a common name in different countries should also have the same composition. The importance of this step was too obvious to need demonstration; everybody was agreed on that point. Of greater importance was the method chosen to attack the problem. In their opinion it was necessary to prepare the ground by collecting in a convenient form the data on which the international conference for unification, when it eventually does meet, will have to base its decisions. A beginning in this field had been made. Each monograph submitted to the Conference dealt exhaustively with a single drug and its preparations giving comparative tables of the formulæ and methods adopted by all existing pharmacopœias, together with criticisms and suggestions as to which appears the most suitable for universal use.

Mr. C. T. Bennett, B.Sc., F.I.C. (Chief Chemist, Wright, Layman and Umney), who had investigated the cinchona preparations and the methods of assay of various pharmacopœias, came to the following conclusions: (1) that the bark should be required to contain 6 to 8 per cent. of total alkaloids; (2) that a liquid extract should be prepared by percolation with 70 per cent. alcohol, hydrochloric acid and glycerine being added to prevent precipitation (its alkaloidal content should be 5 per cent.); (3) a simple tincture (1 per cent. alkaloids) should be prepared with 70 per cent. alcohol.

Mr. H. B. Stevens, O.B.E., F.I.C. (Director, John Bell, Hills and Lucas), dealt in his monograph with the opium preparations, and advised that: (1) in expressing the percentage of alkaloid present the morphine should always be calculated as anhydrous; (2) the extract of opium should contain 20 per cent. of anhydrous morphine, sugar of milk being used as diluent, if necessary; (3) the tincture of opium be made with 45 per cent. alcohol, 70 per cent. being unnecessarily high; (4) the formula for Dover's powder should be: opium 1, ipecac. 1, sugar of milk 8.

Mr. A. J. Jones, Ph.C. (Research Dept., Evans, Lescher and Webb) reviewed the preparations of belladonna, showing the present variations in the formulæ and methods of testing. The author suggests that a soft standardised extract should be retained, and describes the analytical methods which appear most reliable for determining the activity of the drug.

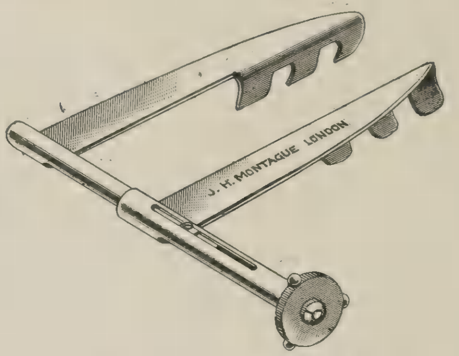
Messrs. J. Cofman-Nicoresti and S. B. Tallantyre, B.Sc., A.R.C.S. (City Laboratories) gave a survey and critical description of the quillaia preparations, while a study of colchicum galenicals from an international standpoint came from Misses E. Hooper, B.Sc., F.I.C., and K. M. King, Ph.C. (Principals of the School of Pharmacy for Women.)

It was finally recommended that the faculties of medicine and pharmacy of every country should be advised to continue and extend this essential preliminary work, and when all the information needed had been collected the Health Department of the League of Nations should be asked to bring together a conference of those concerned, in order to decide which formulæ and methods are most suitable for universal use. The assembly agreed that the permanent committee should consider the proposal and take the necessary steps accordingly.

New Inventions.

A LAMINECTOMY RETRACTOR.

One of the difficulties in performing a laminectomy operation is to obtain adequate retraction of the erector spinæ muscles on each side. If the muscles are peeled away on either side and a self-retaining retractor inserted, an excellent view of the laminæ is obtained, and troublesome hæmorrhage is avoided. The retractor consists of two stout steel blades with wide base and tapering towards the top. The inner edges of the blades have three curved hooks which are inserted under the erector spinæ muscles when the retractor is closed. The extension of the retractor blades are manipulated by a quick travelling screw revolving in a telescopic steel tube. On rotating a wheel at the opposite end of the tube, the blades will open to 5 inches. I have found the retractor a very useful instrument; the adjustment is good.



Messrs. J. H. Montague, of 69, New Bond-street, London, W., have made the retractor here described to my design.

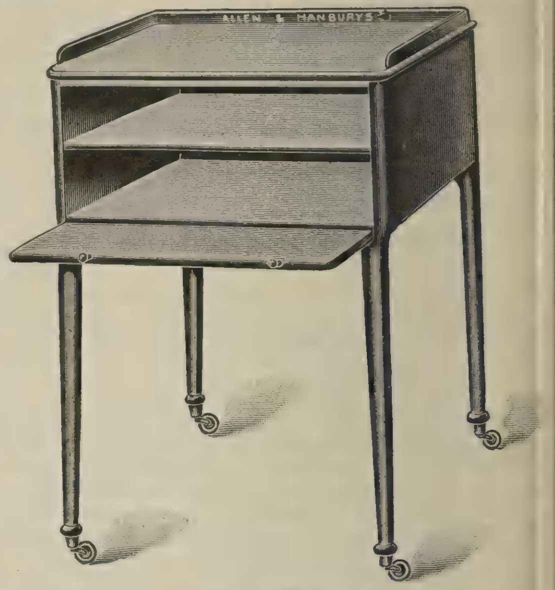
Devonshire-place, W.

INVALID'S BEDSIDE TABLE.

This table has been designed to add to the comfort of those patients who are not helpless, but have to spend many hours in bed. The ordinary table soon becomes crowded with the patient's effects, and everything is displayed to anyone entering the room. The table illustrated is in three tiers: the top and two compartments, and in addition there is a sliding shelf which can be pulled across the bed. It takes up less room than the ordinary small table in use for the purpose, and it has the following advantages: The two compartments w
hold all the personal belongings, such as bool
writing materials, and so on, which any one is likely
need, and these are in sight and control only of t
patient, and are always easy to get at. Spit cu
medicine bottles, and so on, are kept out of sight
everyone except the occupant of the bed. T
sliding shelf pulls over the bed for meals or for writi
upon, and there is no need for bed-tables of any kin



The table runs on easy castors, and a slight push w
place it in any desired position. All corners a
rounded. It can be made of any hard wood, a
polished so that it forms an attractive feature in
sick-room.

The table is made by Messrs. Allen and Hanbury
Ltd., Wigmore-street, London, W. 1.

East Sussex Hospital.—On July 23rd Viscou
Goschen presided at the annual meeting of the recent
opened East Sussex Hospital. In the course of his spee
Lord Goschen spoke of the anxiety on his own part and th
of his audience to preserve the system of voluntary hospita
and of the spirit of voluntary service and self-sacrifi
which, he was convinced, was needed at the present d
perhaps more than ever, and which beside assisting hospita
would assist the country during times of anxiety a
unrest. The greater the advance in hospitals the greater mu
the expense be, but a business man would look at the retu
the country was getting for this insurance against a
population. Lord Goschen recalled that the foundation-sto
of the hospital was laid in 1914, a fortnight before the outbre
of war. The hospital had, however, only just been complete
The annual meeting this year had been delayed to allow of
being held in the new building. The annual report, of cour
referred to the work at the old building at White Roc
It showed that the number of in-patients during the year w
1011, and new out-patients (including 1171 casualty cas
4681. The general income had been well maintained, the
being an increase of £483 upon the ordinary income, the tot
being £13,817. The annual subscriptions showed an increa
of £273, the total received from subscribers being £2326. T
ordinary expenditure showed a considerable drop; a
overdraft at the bank had been liquidated, and the balan
sheet showed a deficit of £145 18*s*. 5*d*. The reserve was p
at £14,419. The report chronicled the purchase of houses f
a nurses' home, the gift of the chairman of the committe
Major W. H. Mullens, J.P. In recording the resignation
Dr. C. Christopherson, senior surgeon, owing to illness, aft
a period of 29 years' service, the report stated that "It
largely due to his ability, influence, and personality that t
East Sussex has obtained its reputation for efficiency."
the discussion on the report it was said that roughly anoth
£10,000 was needed to complete the work, with an addition
sum of £1500 or £2000 for furniture and equipment.

THE LANCET.

LONDON: SATURDAY, AUGUST 11, 1923.

EXOPHTHALMIC GOITRE.

THE present issue of THE LANCET contains two rticles on the treatment of exophthalmic goitre which re to some extent complementary. In one Dr. G. R. urray describes the treatment of the disease by nedical measures; in the other Mr. A. J. Walton leals with it rather from the surgical standpoint. The rticles, however, although complementary, exhibit in remarkable way the necessity for intimate coöperaion between physician and surgeon in treating this ondition. An immense amount of thought has been iven to the attempt to elucidate the ætiology and reatment of the disease, and the literature of the ubject is profuse; but it must be confessed that the roblem of ætiology is still unsolved and that treat- ent, whether medical or surgical, remains almost xclusively symptomatic. But with admission of is fact and of its corollary that surgery may eventu- lly come to occupy a very minor place in the treat- ent of exophthalmic goitre, yet it must also be granted at by far the most striking advances during the last 5 years have been made along the lines of surgical tervention. The foundations of the requisite know- dge and experience have been carefully and painfully id by the pioneer work of Dunhill in Australia, Crile and the Mayo brothers in America, and of erry and Walton in this country, and the results ve been gratifying to surgeons and patients ike. Surgery in the course of its advance has met ith much healthful opposition, but it has proved its orth; and this claim is substantiated by the attitude an authority such as Sir Hector Mackenzie, who, ving been in full opposition ten years ago, is now one the convinced supporters of surgical treatment.

Even apart from the relative claims of medicine or rgery as regards ultimate success, one of the chief ctors lending its weight in favour of surgery is the mparative rapidity with which improvement is tained. The period of the patient's disability is easured by months rather than by years, and the radoxical fact remains that surgical treatment, hough symptomatic, produces a large proportion apparent cures. These results have, however, only en obtained by the closest attention to every detail the procedure. There can be few surgical operations quiring more careful preparation, closer watching the operative conditions, including even the state the weather, or more precise operative technique. l these points receive attention in Mr. Walton's ture, though the limits of a single article, while not venting him from considering the disease from widest possible point of view, have not permitted n to enter fully into the more technical details. position to surgical treatment was formerly based gely on the operative mortality, but this has w been reduced to a point at which statistics cease ave much importance. It may be assumed that the rative mortality is now in expert hands not greater n 5 per cent. A claim made by any individual rator to a reduction to a figure below 3 per cent. sibly depends upon whether he is operating with iew to favourable operative statistics or solely for welfare of the individual patient. When a risky ration forms the patient's only hope of recovery at moral courage may be needed by the surgeon in forming the decision whether the operation is justifiable or not. However this may be, there is a very general agreement among surgeons and physicians that medical treatment should be tried for at least six months in almost every case before any operation is performed. This six months' trial is necessary both as a test of the value of drugs and general measures in each case, and as a preparation for operation if this is eventually to be advised.

On these points controversy is now almost at an end. Difference of opinion still exists, however, regarding the value of treatment by X rays. Dr. Murray regards this as "one of the most reliable means" of treatment we possess; Mr. Walton has found its use "very unsatisfactory," and supports the view that radiation has little or no effect on the thyroid by the observation that he has found no appreciable change in the thyroid of those cases that he has operated upon after X rays had been tried. The general trend of opinion seems to be against a belief in the efficacy of X rays, but this is a matter upon which no final opinion can be expressed. It has long been observed that the changes in the thyroid are accompanied by an enlargement of the thymus gland; this was noticed and recorded 100 years ago by Sir Astley Cooper. But little attention has been given as yet to the effects of radiation upon the thymus which, consisting as it does chiefly of lymphoid cells, might be expected to be more readily affected than the thyroid itself. The whole problem of exophthalmic goitre is a fascinating one, whether regarded from the ætiological, pathological, medical, or surgical standpoint. Every one of these aspects may undergo a sudden and complete change in the near future. The articles now published will at any rate mark the place which had been arrived at in the year 1923.

◆

PHYSICAL RESEMBLANCE IN CASES OF DISPUTED PARENTAGE.

IN the Russell *v.* Russell divorce proceedings, which seem likely to give the House of Lords the opportunity of dealing with more than one point of medico-legal interest, the child was brought into court, and the jury was invited to draw an inference as to its paternity from its resemblance or non-resemblance to photographs of the petitioner taken at a similarly early age. "I cannot stop your considering this question of likeness," said Mr. Justice Hill to the jury, "but I myself regard it as a dangerous guide." The fancifulness of family opinions on suggestions of family likeness is indeed notorious, and the fallibility of partisan belief was manifested in the Russell case, when the respondent was incautiously ready, under a confusing cross-examination, to find a resemblance between her baby and the photograph of a total stranger. Lady Ampthill, the petitioner's mother, declared that the child in court bore no resemblance to her son, but negative evidence in itself is of but slight assistance. Likeness may be some aid in establishing paternity; unlikeness is none. It may be possible to draw attention to an aggregate of similarities—the colouring of the eyes or the hair, the shape of the ear, and so on; but evidence of this kind in courts of law is hardly developed with as much certitude as evidence of identity in hand-writing—a study in which expert witnesses have come sadly to grief before now. General likeness of feature is not uncommonly relied upon in affiliation proceedings, wherein magistrates, we believe, allow it a certain minor corroborative value in a rough and ready sort of way. One would suppose it was an especially dangerous guide in such cases, since the woman is usually making her application to the court at a time when the infant is of so tender an age that immaturity of feature must obscure observation and discount confidence. Much more significant than mere resemblance of feature would be any evidence of some definite hereditary characteristic. If the study of blood-groups yields as yet no very positive result for medico-legal purposes,[1] the recurrence of a malformation might assist decision. Twenty years ago, in a Jamaican case, polydactylism was relied on as an inference of family descent.[2] Racial characteristics would also be of value. A coloured skin and woolly hair would be by no means negligible if there were an allegation of negro paternity. Even in Scotland, where this kind of evidence of physical resemblance is not normally permitted, notice has been taken of such points; for instance, in a case 100 years ago a white man was held not to be the father of a white woman's child, the child being a mulatto.

Those who are interested in this point of medical jurisprudence will find a singularly lucid and informing article by Prof. Courtney Kenny in our learned contemporary the *Law Quarterly Review*, entitled Resemblance as Evidence of Consanguinity, wherein these matters are admirably set forth. The writer traces the doctrine of the acceptability of such evidence back to the famous Douglas Cause of 1769, the most sensational litigation of its time, a topic on which Boswell wrote a pamphlet which he could never induce Dr. Johnson to read. In the House of Lords, Lord Mansfield, enlarging upon the greater scope for drawing helpful inferences from physical likeness amongst human beings than in the rest of the animal world, said "a man might survey 10,000 people before he saw two faces perfectly alike," while Camden, then Lord Chancellor, in language more rhetorical than judicial, spoke of the physical likeness in the case as "an impression stamped by God himself to prove the legitimacy of the child." In 1915, it may be recalled, evidence of this kind was tendered in the Slingsby case, when an action was brought in the name of a boy of 4 years of age, asking that he be declared the lawful child of Commander Slingsby, who supported his claim as against certain relatives who were hostile to it. The judge, Sir Bargrave Deane, then took the unusual course of obtaining the services of Sir George Frampton, the well-known sculptor, to assist him in the comparison of the features. The judgment, which was in favour of the boy's legitimacy, dwelt upon his extraordinary likeness to Commander Slingsby. Both the Court of Appeal and the House of Lords were prepared to allow weight to the judge's own opinion of the likeness, though the calling in of the sculptor, who had neither been sworn as an expert witness nor formally appointed as an assessor, was thought irregular.

Thus, after a long series of decisions it has become clear that the English law, cautiously and for what the evidence may be worth, allows testimony of physical resemblance in disputes about parentage. In a well-known text-book of high authority—Taylor on "Evidence"—it is suggested that this legal position is automatically reached as soon as it is proved to the court as a matter of science that children are apt to inherit the features of their parents. In criticising this statement Prof. Kenny points out that there is no case on record wherein the courts have required any such preliminary proof of the general principle. Judicial ignorance, nowadays perhaps less overworked than formerly, is not so blindfold as that. As Prof. Kenny observes, "Tribunals sufficiently familiar with the course of nature to be able to take judicial notice that a woman of 70 will have no more children, and that a husband's non-access for a year disproves the legitimacy of his wife's child, will need no aid from scientific witnesses to assure them that 'Like is apt to beget like.'"

THE MECHANISM OF ALIMENTARY SECRETION.

A glance at recent work in physiology reveals a number of highly critical publications on the subject of alimentary hormones. After the introduction of gastric and pancreatic secretin some years ago the hormonic theory of secretory stimulation seemed to take an assured position in physiology, at least in this country. Very little work on similar lines appeared until quite recently; perhaps the work of Ivy should be mentioned first, since he repeated a great deal of Edkins's work, which he failed to confirm, and came to the conclusion that gastric secretin was not the normal method of producing a secretion from the stomach. With regard to the question of pancreatic secretin, there is abundant confirmation of the fact that an injection of an extract of duodenal mucosa does cause a secretion from the pancreas. The doubt arises as to whether this is the normal mechanism of pancreatic secretion, for there seems to be a gap in the logic at this point. It will be remembered that Bayliss and Starling stated that many substances were capable of producing secretin, but that HCl was by far the most potent and important. Damade and de Grailly, in a paper on duodenal tubage read recently before the Société de Biologie,[1] give the results obtained by the injection of substances directly into the duodenum. They passed a duodenal tube on the starving subject, and aspirated as much fluid from the duodenum as possible. They then injected various test fluids into the duodenum through the tube, and withdrew specimens of the resulting secretion at quarter-hourly intervals. These specimens were measured and were analysed for bile, lipase, trypsin and titratable alkalinity. The observers experimented with milk, skimmed milk, olive oil, and a solution containing HCl and peptone. They found that olive oil and milk increased the volume and the enzyme content to a very marked extent, whilst hydrochloric acid appeared to be without action. In some of the experiments olive oil doubled both the volume and the concentration of the constituents of the secretion. The conclusions to be drawn from the experiments is in direct opposition to the popular conception of the secretin hypothesis, which holds hydrochloric acid to be far the most powerful of secretin producers. The problem of pancreatic stimulation in achlorhydria is brought to mind. Similar results were obtained by Bennett and Dodds, who used the respiratory method of recording secretion below the pylorus. These workers showed that there was no difference in the effect on pancreatic secretion when acid or alkaline fluids were introduced into the duodenum. Unfortunately, it is practically impossible to devise any method of investigating secretion below the pylorus in which the sources of error are fairly low. Direct tubage of the duodenum is open to more fallacies than tubage of the stomach, since the contents at any particular moment are influenced by so many rapidly varying factors—namely, entrance of stomach contents, bile, pancreatic and duodenal secretions, together with the more or less rapid passage of the resultant mixture through the duodenum. The last ten years have seen considerable advances in the study of human digestion, and as more physiological research is done with normal men as subjects it becomes more and more apparent that a large number of the text-book views on digestion—based on animal work—are quite inapplicable to man.

Annotations.

"Ne quid nimis."

PRESIDENT HARDING.

THE late President Harding, whose death occurred with tragic suddenness as he was apparently on the high road to recovery from an attack of bronchopneumonia, came of a medical stock. His father, George Tryon Harding, is still in practice at Marion, a township of 29,000 inhabitants in Ohio, where the President was born and brought up. Dr. Harding s now in his seventy-ninth year, having qualified at Cleveland University in 1873. A younger brother of he late President bears his father's name and is in practice at Columbus, a city of 240,000 in the same State; he qualified in 1900 at the Ann Arbor University of Michigan and is a specialist in neurology and psychiatry. It is not fanciful to see in the late President's broad outlook some reflection of the medical atmosphere in his early home life.

INDUSTRY AND HEALTH.

MANY influences are pointed to when reason is sought for the steady improvement which has taken lace since the middle of last century in the health of he nation. Improved sanitation, better housing, ure water-supply, rise in value of real wages with etter feeding, less intemperance, better care of the ndividual and by the individual due to better educa- on—all are credited with their contribution; but here nd there authorities such as Greenwood have stressed he importance of improved conditions of labour rought about partly by natural progress as industrial methods have developed, but more directly by com- liance with our code of factory legislation. Few ersons are in a position to judge of the progress, since ew are familiar with the insides of our great factories. here exists, however, a body of expert inspectors ways at work pressing for and obtaining improve- ments; probably it constitutes the most effective ranch of the public health service. It is formed of wo groups, inspectors of factories and inspectors mines.

We have before us, just published, the annual report the Chief Inspector of Factories,[1] which tells of the ork done during the past year. Signs are reported of turn in the industrial tide and of opportunities being ken to prepare for future development. The tend- ncy continues for larger establishments to increase in umber and size while the smaller workshops get wer—a movement advantageous to improved con- tions of work. The report consists of four chap- rs in which information is given of the more striking ents of the year and of steps taken to administer the w and obtain compliance with the various codes of gulations; then follow three chapters dealing with ecial investigations, one into the dust content of the mosphere of workplaces, another concerned with ysiological costs of different methods of weight- rrying, and the third with dangers from explosions oil-carrying and oil-fuel ships. We note with preciation that the factory department is carrying t such work. The time has gone by when advances industrial legislation can be based upon "a general nsensus of opinion"; the obviously injurious matters e under control. Only by accurate knowledge based careful research can further pronounced progress be ected. The work of Dr. E. L. Middleton is a good stance in point, since he has been able to advance owledge concerning the type and size of dust rticles inhaled and the kinds of symptoms and validity which follow. This knowledge should allow tion to be concentrated upon the most injurious types dust. Somewhat unfortunately for the reader the esentation of Dr. Middleton's research has been vided up; one part appears in the present report and deals with the dust present, the other part, concerned with his clinical findings and physical examinations, has just appeared in a separate report.[2] The reason for this separation is obscure. Dr. E. E. Hewitt's research into weight-lifting is another valuable piece of work. Here is a subject about which much has been said, but little really is known. At last, by appeal to the laboratory and to experiment, the foundations have been laid of useful information as to the energy-cost of labour and to the degree to which this cost can be modified by method.

The work of the medical staff is told of by Dr. T. M. Legge, especially with reference to the control of different forms of industrial poisoning, of which plumbism receives most attention; the cases for the year numbered 247, as compared with 639 in 1902. The international aspect of industrial health is borne evidence to by an inquiry conducted into photo-engraving for the International Labour Office, part of a more general inquiry conducted in several other countries,[3] concerning which it is sufficient to note that the danger from nitrous fumes is recognised and under control in this country.

AN IRISH POOR-LAW HOSPITAL SCHEME.

THE first annual report covering the year ended March 31st, 1923, of the County Galway Board of Health is addressed to the Minister for Local Government, President Cosgrave, who was himself responsible for the order, "Abolish the Unions." Mr. Cosgrave writes in a foreword to the report:

> "It has been well and truly said that kindly care for the poor is the best sign of true civilisation, and, again, that the condition of a nation's poor indicates the character of the national mind. With the coming of Freedom the people of County Galway were quick to realise that, at last, it was in their power to end for ever the contemptuous treatment of the poor resulting from the workhouse system, and they set about inaugurating a new system with energy and zeal. I have great hope that, in County Galway and throughout the Free State, the new schemes, established for the better relief of the poor and the better care of the sick, will be administered prudently and humanely, and that these schemes will win for themselves the confidence of the people. Let us hope that true kindly charity may spring from the good fortune on which, we believe, our country is entering."

The report states at the outset that the whole "workhouse" system was inherently bad and would appear to have been designed to put poverty and misery and vice conveniently out of sight rather than to relieve or comfort or retrieve. A history is given of the ineffectual attempts to amalgamate the unions, beginning in August, 1899, and culminating in the County Council Order of October, 1921, appointing the County Board of Health with instructions to abolish the unions and to set up one central county hospital, one central county home, a home for children and unmarried mothers, and to arrange for the care of other classes of persons chargeable to county rates. The Board of Health worked at high pressure, and within eight weeks, by the middle of December, the unions of County Galway had gone for ever without any sworn inquiries, without any expenditure on evidence, and without even a sealed Order.

The central hospital is located at Galway, the county home at Loughrea, and the Board have made arrangements with the Bon Secour sisters to take charge of the children's home, for which the Glennamaddy Union Buildings have been utilised. Thirty per cent. of the customers of the workhouses disappeared when asked to move, a proportion of whom will probably become recipients of home assistance. Appointments have been made as far as possible from existing staffs, so as to avoid compensation. The claims of 206 disemployed officers have been considered. Much union property has been lost through burning. Home assistance (formerly outdoor relief)

Annual Report of Chief Inspector of Factories for 1922, M. Stationery Office. [Cmd. 1920]. 1923. Pp. 153. 5s.

[2] Report on Grinding of Metals and Cleaning of Castings and the Effects of Dust Inhalation upon the Workers E. C. Macklin and E. L. Middleton. H.M. Stationery Office. 1923.

[3] Dangers to Health in Photo-Engraving, International Labour Review, vol. iii., No. 1, pp. 116–125.

is to be all in kind and not in cash. A medical and surgical staff has been appointed for the hospital. The question of "paying patients" gives trouble, and it is difficult to obtain payment from every patient who is able to pay. The salary of the medical officer of a full dispensary district has been fixed, temporarily, at £300 per annum and of a dispensary midwife at £52. The new county home at Loughrea is an attempt to bring comfort and happiness into the lives of the inmates, who have comfortable dining and recreation rooms and dormitories, games and grounds for pleasant exercise—in fact, a great contrast to the old typical workhouses. The Board are confident that the children's home, placed in charge of the Bon Secour sisters, will prove a valuable addition to the social service machinery of the county, and the necessary reconstruction to put it into an efficient condition is now receiving attention. For harmless lunatics and epileptics the county unit is too small and a provincial institution will be the probable solution. From an economic point of view the changes have resulted in the reduction of the annual demand on the ratepayers from £102,000 (March, 1921) to £59,000 (March, 1924). Economy is not the most important consideration, and the Board claim that, although much requires to be done, they have already achieved a fair measure of success in securing better care for the old and infirm and for the sick, and more kindly thought for the shelter and retrievement of the unfortunate.

The Galway Board of Health have made an energetic start, and all social reformers must heartily wish them success. It may be that just as our farmers go to Ireland to learn about coöperation we may shortly be sending deputations there to learn how to deal with the long overdue changes needed in our Poor-law system.

SPLENIC ANÆMIA.

Dr. William C. Chaney[1] has devoted his thesis for the degree of master of science in medicine at the University of Minnesota to a clinical and pathological study of anæmia based on 69 cases in which splenectomy was performed at the Mayo Clinic from Nov. 14th, 1905, to Sept. 1st, 1920. Allusion to this series was made by Dr. W. J. Mayo at the recent congress of the International Society of Surgery. The average age of the patients was 33 years, the youngest being 2½ and the oldest 69. The distribution was about equal in both sexes, 36 being males and 33 females. There was apparently no familial tendency to the disease. The most frequent symptoms were enlargement of the spleen and a mass in the left side of the abdomen (29 cases), gastric hæmorrhage (20 cases), and weakness (19 cases). Abdominal pain was rarely mentioned as the chief complaint, but 32 patients gave a history of such attacks at some stage of the disease. In many instances the pain was probably due to perisplenitis, but in some cases it was due to other causes, such as gall-stones or chronic appendicitis. With a single exception in which it could not be felt owing to the presence of ascites, the spleen was palpable in every case, its average weight being 1015 g. Its relative position in the abdomen was preserved in spite of its progressive enlargement. On operation 26 patients were found to have enlarged livers and 30 definite cirrhosis of the liver, in only 13 of which the liver was larger than normal. The size of the liver did not seem to bear any relation to the size and weight of the spleen. Ascites was present in 24 cases, 23 of which had cirrhosis of the liver. In the remaining case the liver was enlarged but apparently not cirrhotic. The average red-cell count in the 69 cases was 3,700,000, the hæmoglobin 53 per cent., and the leucocytes 4900. The coagulation time and the fragility test were normal and the Wassermann reaction, which was performed in 60 cases, was negative. A composite chart of the leucocyte count showed that there was an initial rise of the leucocytes immediately after the operation, and that the number gradually increased up to 75 to 100 days after the operation. Lymphocytosis was not characteristic of this series. The highest mortality occurred within 40 days of the operation, during which period there were 12 deaths, 7 of which were in cases with marked hepatic cirrhosis. The principal pathological findings were as follows: On naked-eye examination fibrosis was very evident and the trabeculæ especially prominent. The degree of fibrosis of the reticulum seemed to vary with the amount of arterio-sclerosis, but there was no evidence to show that the fibrosis originated in or around the vessel walls. The amount of lymphoid tissue was usually below normal. The number and size of the Malpighian corpuscles were found to decrease as the size and weight of the spleen increased.

NON-TRAUMATIC DIAPHRAGMATIC HERNIA.

IN a paper read before the annual meeting of the Radiological Society of North America Dr. E. H. Kessler,[1] of St. Louis, remarks that while congenital diaphragmatic hernia is rare, hernia of the diaphragm caused by trauma, such as crushing injuries, gunshot wounds, and injury by the aspirating needle is not infrequent. In the course of two years he has met with four cases without any known history of injury. Two of the patients had been referred to him for gastro-intestinal examination on account of gastro-intestinal disturbance, the third for the confirmation of a diagnosis of pneumothorax, and the fourth had been sent to him for an examination of the heart. In two cases the hernia occurred through an abnormally large opening for the œsophagus, and two had an opening through the dome of the diaphragm. Dr. Kessler points out that we cannot be absolutely certain of the existence of non-traumatic hernia, as an injury may have been received without the patient's knowledge. The symptoms are not very distinctive and the history may be misleading. The condition, however, is easily recognised by the use of the X rays. As a rule, there is pain in the lower part of the left side of the chest which will have a resonant note if the stomach is full of gas, and there will be an absence of heart sounds in this area. Vomiting is not always present. There may be distension and dyspnœa, and, at times, regurgitation. Unless strangulation occurs the condition is not fatal. Dr. Kessler has collected 15 cases from recent literature of diaphragmatic hernia, six of which were congenital, eight traumatic, and one, like his own, without any history of injury.

THE TEACHING OF SURGERY BY KINEMATOGRAPHIC FILMS.

Doyen was the pioneer of the kinematographic teaching of surgical technique, and as far back as 1898 some of his operations were filmed for lecture purposes. Little was heard of surgical films in this country until a demonstration given three years ago by the Selig and Phillips Film Companies of the work of American surgeons, in which H. Lilienthal was seen performing a gastrostomy and F. H. Albee fixing an inlay bone-graft. An apparatus for taking the films has recently been perfected by Dr. Alex. v. Rothe, director of the Wilmersdorf Hospital in Berlin. The lens of this apparatus is contained in a spherical aseptic case suspended from the ceiling and focused by means of a periscope; it does not interfere in any way with the surgeon's freedom of action. The success has been such that the German Government has sanctioned the installation in six leading Berlin clinics. Some films obtained with the v. Rothe apparatus were shown by Dr. Bertram Stone last week at a private meeting of medical men in Portsmouth. They were noticeable for showing every detail of the operations from a vantage point which is denied to the ordinary onlooker, and, indeed, to the surgeon's assistant himself. The possibilities for teaching purposes opened up by this method are very great. Text-book descriptions convey little instruction when compared with kinematograph films, and the practising surgeon who nowadays is in the habit of travelling abroad at considerable expense to obtain inadequate glimpses of the technique of other operators than himself should in the future be able to study any particular operation as performed by the most eminent specialists in Europe and America without the necessity of going away from home. The surgeons whose work was displayed at Portsmouth were Krause, Bier, and Donitz, and the surgical procedures, which were shown in every detail from beginning to end, included a craniotomy for Jacksonian epilepsy with electrical localisation of the affected area of cortex, wiring a fractured patella, and gastro-enterostomy for a chronic gastric ulcer. The next desideratum is to obtain coloured films.

THE EXPERIMENTAL REPRODUCTION OF MALARIA.

THE problem of relapses in malaria is one of the most interesting from a practical point of view in addition to being one of the most complex. In the daily combat that individuals, associations, and nations engage in against the periodic epidemic, the resistant link in the chain that binds one yearly epidemic to another is represented by the malarial relapse ; in treatment and prophylaxis the national measures which are tried are shattered against its exasperating insistence. The cure of the disease, therefore, and the prevention of the annual epidemics will proceed on rational lines as soon as the problem of the pathogenic mechanism of the relapse is solved. That the relapse is caused by the reproduction of the gametes in the circulation is no new idea, but the morphological demonstration of the fact has never met with universal acceptation and the problem in regard to the semilunar bodies is more than ever obscure owing to futile attempts to seek such evidence. There is an alternate method—viz., to attempt the reproduction of malaria by means of inoculating gametes only, and Prof. T. Pontano, of the University of Rome, has lately conducted some very interesting experiments on this point.[1] The experiments came under three categories, the first consisting of six inocuations of malarial blood quininised for a long period and containing crescent forms only, the second consisting of three experiments with malignant tertian blood which after quininisation was free from parasites, and the third of two experiments with malarial blood containing annular parasites and not quininised. Of these 11 experiments, the first six in which blood containing only crescent bodies was inoculated gave our positive results and two negative ; the period of quininisation varied, being never less than seven days, rom 16 to 74 days in the others, and had the object of destroying the asexual forms of the parasite. The amount of blood inoculated was from 8–10 c.cm., the ncubation period varied from 7 11 days, and the idenity of the malarial attack was proved by discovery of the parasite in the blood, fever, and enlargement of he spleen. The second series of experiments conisting of three inoculations of malarial blood which howed at first numerous asexual forms of plasmodium præcox and which after prolonged and intense quininisation became free from parasites, all gave negative results after clinical and hæmatological observation lasting from a month to a year. The onors were treated with daily doses of 2 g. of quinine and were sterilised much more easily. The last two xperiments of injecting blood containing only annular orms of plasmodium præcox and not quininised both ave positive results. These experiments seem to show hat the crescent body is responsible for the transmission of malaria and no longer represents in the irculation a sterile body but a gametic parasite, apable of generating schizonts, and further, that the sexual parasites or schizonts disappear from the irculation during and after intense quininisation. In hese researches in which plasmodium præcox was noculated the same parasite was always found in the relapses and transformation of one kind of malarial parasite into another was never seen. The chief point of interest in these observations is that intravenous inoculation of crescent-containing blood after prolonged quininisation and free from asexual parasites caused malarial infection in unaffected subjects, while, on the other hand, blood containing only schizonts but quininised until the disappearance of the parasites did not cause any infection ; the crescents or gametes of plasmodium præcox were capable of proliferation and of generating asexual fever-producing parasites. Moreover, it was found that relapses occurred obstinately after inoculation with crescent-containing blood, while the experimental malaria caused by schizonts was easily curable. The schizonts which accompany the crescents in the circulation disappeared with difficulty after quininisation, while malarial blood was easily sterilised when schizonts alone were found in the peripheral circulation. These two facts find their explanation in the reproductive capacity of the gametes and in their resistances to the specific remedy.

SAILORS AND VENEREAL DISEASE.

THE Merchant's Shipping Act (Amendments) Bill, which received the Royal Assent and became law on August 2nd, removes a disability in the treatment of masters and sailors of the mercantile marine. Subsection 1 of Section 34 of the Merchant's Shipping Act of 1906, whilst it provided for the gratuitous treatment of injuries and illnesses aboard ship and in hospital, categorically excluded venereal disease, with the result that sailors were not only denied treatment but were liable to be left friendless and without funds whilst in foreign hospitals. Foreign doctors and irregular practitioners charged excessive sums for treatment that was in many cases incomplete if not worse. The Royal Commission which sat between 1913 and 1915 advised gratuitous treatment in the British Isles for venereal disease, and last year 162,000 persons availed themselves of this privilege from which British sailors in British ships were excluded. The new Act is no more than a simple act of justice to the British seaman. Although the Bill consisted of a single clause it has entailed a good deal of hard work from Sir John Collie who was in charge of it, and who was fortunate in obtaining the hearty support of the Minister of Health and of Lord Wolmer, Parliamentary Secretary to the Board of Trade, as well as of the Shipping Federation and the Seafarer's Joint Council. From the public health point of view this small Bill is of considerable importance, for the perfunctory treatment which these cases received, and the concealment which the law encouraged, must have had a material effect in spreading disease when the sailors returned to this country. We congratulate the party whose efforts placed it on the Statute book.

THE USE OF THYMUS EXTRACT AS A THERAPEUTIC AGENT.

VERY little is known of the physiology and pathology of the thymus gland nor of the indications for its administration as a therapeutic agent. Felix Boenheim,[1] of Berlin, gives some results of treatment carried out by him with extracts of this organ in various pathological conditions. There is at present no clinical evidence of deficiency of the gland, and therefore it cannot be used as a substitute, as in the case of the thyroid, but experimentally it can be shown that the thymus counteracts some of the other endocrine glands, and so can be used when they are showing signs of excessive secretion. Combined with iodine, Dr. Boenheim finds that thymus has a very beneficial effect on colloid goitre and on exophthalmic goitre, the thymus preventing all traces of iodism. It has, however, no effect on the cysts in cases of cystic goitre, for while the general enlargement diminishes the cysts become more prominent. The treatment has been effective where

[1] Il Policlinico, Medical Section, xxx., June 1st, 1923

[1] Deutsche medizinische Wochenschrift, April 13th, 1923.

X rays have proved valueless. In certain cases of hyperacidity of the gastric secretion associated with hyperthyroidism, administration of thymus restores the secretion to its normal content. Dr. Boenheim explains this phenomenon on the basis that one of the functions of the thymus is to diminish the rate of mobilisation of the chlorides, whereas the thyroid increases it. Increased function of the thyroid leads to increased mobilisation of chlorides. This causes hyperchlorhydria, which in its turn leads to hyperacidity and increased secretion of the gastric glands. The thymus counteracts this chain of events. In other forms of hyperacidity, such as that due to gastric ulcer, and the neural form (tabes), the thymus has no effect. In phthisis, thymus has proved a powerful aid, leading to an increase in the appetite and of the weight. This effect is probably due to its action on the gastric secretion in diminishing the hyperacidity which is often found in tuberculosis. Caution must be used during pregnancy, for here the thymus may have ill effects, and is not capable of antagonising the thyroid. The asthenias show great improvement with thymus administration. Dr. Boenheim recommends the preparation of Burroughs, Wellcome and Co., 1–2 tablets thrice daily, in preference to any of the German preparations.

THE CORPUS LUTEUM AFTER HYSTERECTOMY.

It is usually assumed that extirpation of the uterus is without any very noticeable effect on the ovaries. Experiments in the guinea-pig by Leo Loeb, of Washington University,[1] show that a complete or almost complete extirpation of the uterus may be followed by a very characteristic effect—namely, a long-continued preservation and activity of the corpus luteum. Instead of beginning to degenerate 14 or 15 days after ovulation, the corpus luteum may remain well preserved and even show mitotic proliferation for 60 days or longer after the last heat. The cyclic corpus luteum thus equals or surpasses in vitality the corpus luteum of pregnancy, which latter has in the guinea-pig a duration of about 65 days. This effect—long preservation of the corpus luteum—occurs if the uterus is extirpated a few days after ovulation. If the uterus is extirpated in very young guinea-pigs when an ovulation has not yet occurred, the first ovulation takes place, notwithstanding the extirpation of the uterus, from 9 to 29 days after the operation. The corpus luteum which thus originates remains preserved for a long period of time with mitotic figures in the lutein cells. Extirpation of the uterus does not directly prevent ovulation, but it has such an effect indirectly by preserving the life of the corpora lutea. In other respects the ovaries in hysterectomised guinea-pigs are normal. Follicles grow in the normal manner, mature, and undergo atresia. These corpora lutea not only live, but they also function and prevent the occurrence of an ovulation during the whole period of their life; but if the corpora lutea are extirpated completely, a new ovulation takes place at an early period notwithstanding the absence of the uterus, an additional proof that the hysterectomy as such does not prevent ovulation. If, however, the maturation of follicles is prevented through underfeeding, a new corpus luteum does not develop in a young guinea-pig which has not yet ovulated, even after extirpation of the uterus. This marked prolongation in the life and function of the corpus luteum may not only be obtained after a complete hysterectomy, but even in cases where a very small amount of uterine tissue has been left unremoved. In hysterectomised animals the mammary gland develops quite markedly, and mitotic proliferation may be observed in such glands as late as 74 days after the last ovulation. If one-third or one-fourth of the length of the uterus is left unremoved the full effects of this operation are not observed, although the life and function of the corpus luteum is somewhat prolonged even under these conditions. It would seem, therefore, that a relatively small part of the uterus can at least to a great extent take over the function of the whole.

THE RÔLE OF PULEX IRRITANS IN THE SPREAD OF BUBONIC PLAGUE IN GREAT BRITAIN.

In an instructive summary of our present knowledge upon the epidemiology of plague, Dr. William Lethem,[1] assistant medical officer of health for the City and Port of Liverpool, remarks that the disease, as it occurs in Britain now, differs notably from the pest of the Middle Ages. This decrease cannot be attributed solely to public health legislation, but in part at least to the almost complete disappearance of the old English black rat (*R. rattus*), which has been swept away by the brown or Norwegian rat (*R. decumanus*) since its introduction in 1727—one of the most remarkable instances in zoology of the replacement of one closely allied species by another. *Ceratophyllus fasciatus*, the plague flea of colder climates, is by no means such a successful carrier of plague as *Xenopsylla cheopis*, the plague flea of the tropics, nor does it bite man so readily; it lives by preference not on the rat itself, but in the nest, often situated underground. Under experimental conditions, this flea is known to carry infection for 47 days, considerably longer than *X. cheopis*, but owing to its habits man rarely comes into contact with *C. fasciatus*. In the tropics the black rat is a domestic species which lives in close contact with man, and harbours in its coat *X. cheopis*, a ready carrier of plague; the parasite, moreover, forsakes the rat immediately after its death. These differences may account for the scarcity of plague in Britain, but they do not explain why, when a case has occurred, the disease tends to be confined to a single household and to those in most intimate contact with the patient. Dr. Lethem thinks that the human flea (*Pulex irritans*) has hitherto been ruled out as a source of danger on very little evidence. It dies off at 85° F., and is less common in India than in Great Britain. When the outbreaks of plague since 1900 are considered, we find that, unlike tropical epidemics, either no plague rats are found or they are present in insufficient numbers to bear any relation to the human cases. It is suggested that in these instances *Pulex irritans* acts as a direct vector of the infection from one man to another. The most convincing instance of this is the Suffolk outbreak in 1910, in which seven bubonic cases occurred in one house in rapid succession. The human flea can only retain the infection for a few days, whilst the rat fleas can do so for 6 to 13 weeks. On the evidence it seems probable that epidemics of bubonic plague in Great Britain are not caused by the rat flea but that infection is spread by the human flea—*Pulex irritans*.

MINERS' NYSTAGMUS: THE QUESTION OF COMPENSATION.

The second report of the Miners' Nystagmus Committee of the Medical Research Council, just published, discloses what appears to be a serious flaw in the Workmen's Compensation Act. The report is mainly the work of Mr. G. H. Pooley, but is endorsed by the other members of the committee—namely, Dr. J. S. Haldane, Prof. E L. Collis, and Dr. T. L Llewellyn. After contrasting the relative prevalence of *compensated* incapacity from this cause, on the one hand in France, Belgium and Germany, where it is small, with that in England, where it is great and increasing, it goes on to point out the explanation of this difference. This lies not in an increase in the number of those actually affected, but entirely, the report implies, in a very decided increase in the number of those seeking and obtaining compensation in this country, and this from three causes. In the first place the new schedule in 1913 altered the nomenclature of the disease from "nystagmus" to "the disease known as miners' nystagmus . . . . whether the symptom of oscillation of the eye-balls be present or not." The result was to include cases claiming compensation for psychoneurosis. Secondly, the maximum compensation money was raised in 1919 from 20*s.* to 35*s.* a week, and while wages and the cost of living have been reduced since then the compensation has remained the same. Consequently, it is found to be not rare for miners disabled from some general disease not arising from their work to be obtaining compensation for nystagmus which, if they had been otherwise in good health, they would not have claimed. In the third place, whereas abroad only severe cases of nystagmus are admitted for compensation, in this country slight cases are admitted under the belief that any degree of oscillation of the eye-balls renders the miner unsuitable for underground work and that it tends to get worse if underground work is continued. Owing to the combined action of these three causes, not only the number of fresh claims but the average duration of incapacity has risen enormously, facts which, the report implies, have no relation whatever to the actual prevalence of the disease, but solely to the facilities for obtaining compensation. In the opinion of the Committee the compensation is in many cases entirely unnecessary, as, in their opinion, mild cases of nystagmus do not necessarily involve incapacity for work, and in fact often persist for years without the knowledge of the patient. The most important conclusion is that "most cases of miners' nystagmus are only partially incapacitated; they benefit physically and psychologically by work. Some require work above ground; others are fit for suitable work below ground. All men in this group should receive every encouragement to start work as soon as possible."

---

[1] Proc. Soc. for Expt. Biol. and Medicine, vol. xx., No. 8, 1923.

[1] The Medical Officer, July 21st, 1923.

It will be seen that this report throws down a challenge. If its conclusions are justified a drastic alteration in the law of compensation is called for, but the legislator may fairly demand some sort of unanimity of opinion among the experts. The important points at issue are first, whether the psychoneurotic symptoms are an essential part of the disease, and secondly, whether or not slight cases of nystagmus tend to become worse with a continuance of underground work. We do not propose to pass judgment as between the two opposing schools of thought, but merely to call attention to a matter which is not only of medical but of economic and sociological importance. It is alleged that thousands of pounds are being spent every week in a manner worse than wasteful. Can this challenge be answered?

SMALL-POX IN ENGLAND AND WALES.

THE epidemic of small-pox is definitely on the wane; 51 new cases were reported in England and Wales during the week ended July 28th, as compared with 116 new cases (with 1 death) in the preceding week, and 148 new cases (with 1 death) in the week before hat. These 51 cases occurred in the following areas: Derbyshire 6 (Long Eaton); Gloucestershire 22 (all n Gloucester, and including 1 case previously notified as chicken-pox); Notts, 16 (Kirkby-in-Ashfield 9, Warsop 6, Basford R.D. 1); Yorks, North Riding, (Middlesbrough); Yorks, West Riding, 4 (Bentley-with-Arksey 3, Doncaster 1); Monmouthshire 2 Newport 1, Rhymney 1). There is diminishing ncidence in all the areas affected and no new areas are nvolved. The outbreak is now following the course which is to be expected when the disease is frankly ecognised and dealt with on the lines of established hygienic experience. The County of Devon, for nstance, is bestirring itself, after years of fruitless discussion, to provide isolation accommodation hroughout the administrative area, in which only two ocal authorities, Torquay and Plympton, have as yet made adequate provision. Vaccinations in Gloucester are stated to have averaged 2000 a month since April last.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXXII.

TREATMENT OF EXOPHTHALMIC GOITRE AND OTHER FORMS OF HYPERTHYROIDISM.

IN undertaking the treatment of exophthalmic goitre and the allied conditions of simple hyperthyroidism and toxic adenoma, it is important to have a clear conception of the aims of the treatment and of the principles which underlie its practical application. In this group of maladies we have to deal with one common factor, the abnormal activity of the thyroid gland, in consequence of which an excess of secretion is poured into the blood and conveyed to the tissues of the body in which the thyroidal hormones raise the metabolic rate above the normal level. The problem we have to consider is how to restore the functional activity of the thyroid gland to a normal level as soon and as safely as possible. Whatever the true causation and pathology of exophthalmic goitre may be, experience shows that, provided no irreparable damage has been sustained by the heart, kidneys, or pancreas, when the function of the thyroid gland is restored to a normal level recovery takes place.

In estimating the results of treatment, the pulse-rate should be taken daily under the same circumstances when the patient is at rest, and the weight recorded each month. A steady diminution of the pulse-rate and increase in the weight are favourable indications. The tremor, nervousness, and mental excitability are additional guides as to progress. Regular monthly estimations of the basal metabolic rate, when circumstances allow of accurate observations being made, are of great value in assessing the value of treatment.

General Management.—The circumstances of each individual case should be fully investigated, so that all conditions which are likely to stimulate the thyroid gland may, as far as possible, be either removed or guarded against. Some of the most injurious factors which can often be controlled are those arising from nervous strain and anxiety, physical exertion, septic absorption, sexual excess, erroneous diet, and residence near the sea or in a hot climate. Other factors, such as accident, fright, shock, and worry, are beyond our power to prevent, though their ill-effects may be diminished by the exercise of additional care immediately after their occurrence. Thus, nervous strain arising from some special occupation may be relieved by change of work in mild cases, or by complete rest in severe ones. Change of surroundings, as from the town to a quiet country place, is often of service. The seaside should be avoided, as the symptoms are apt to be aggravated by a visit to the sea. Any occupation which involves such efforts as accelerate the already frequent pulse must be given up. In severe cases complete rest in bed for several weeks or even months is advisable. In mild cases, rest in bed for 12 hours at night and for two hours in the afternoon may be sufficient. Rest in the open air in a quiet garden is suitable for those who can stay in the country, and in warm weather as little exercise as possible should be taken. Any septic focus in the mouth, naso-pharynx, or elsewhere must be dealt with at the commencement of treatment.

Diet.—Red meats and their extracts should be avoided. Fish, eggs, chicken, and fat bacon can be allowed. Bread, vegetables, and fruit are suitable, and butter may be taken sparingly. If there is emaciation, milk may be given up to as much as three or four pints in the day. Half an ounce of cod-liver oil should be given daily in one or two doses. Alcohol and coffee should not be taken.

Medicinal Treatment.—A few drugs are useful in the treatment of the malady, and others are helpful in the relief of special symptoms and complications. Quinine hydrobromide, gr. iii.-v., thrice daily is of much value, though some patients are intolerant of it. Liquor arsenicalis, ♏. iii.-v., may be given twice or thrice daily for three weeks each month for several months. If nervousness or tremor are marked symptoms, it is advisable to add sodium bromide, gr. v., to the mixture. The various organic preparations which have been employed, such as rodagen, half a drachm, or thyroidectin, gr. v., thrice daily, and the like, have yielded no consistently good results. The whole of the milk of a thyroidless goat has an excellent effect in some cases when an adequate supply has been obtainable. Suprarenal tablets have proved helpful in some cases. No preparation which contains any thyroid extract or iodine should be given.

Radiological and Electrical Treatment.—A prolonged course of treatment by X rays or radium in skilled hands is one of the most reliable means we possess of controlling the activity of the thyroid gland, and in many cases, of hastening its return to a normal condition. When X ray treatment is available, a dose of one and a half Sabouraud units, measured before filtration and passed through a layer of 3 mm. of aluminium and boiler felt placed on the skin, may be given twice a week. Later on this dose may be given at lengthening intervals, according to the progress made. Larger doses may be given at longer intervals, the object being to give as large a dose as possible without injury to the skin. This treatment finds its most favourable opportunity in cases of simple hyperthyroidism and in the milder cases of Graves's disease. It is also of value in severe cases. In cases of Graves's disease in which the goitre is unusually large, and in cases of toxic adenoma, the results are unsatisfactory, and if a subsequent operation becomes necessary, the capsular adhesions render it more difficult. For patients who live at a distance radium is more convenient, as the plates have only to be applied for 24 hours once every six weeks. A radiotherapeutic course requires six months, a year, or even two years to produce its full effect. Radium is unsuitable for acute cases of exophthalmic goitre, as the initial increase of secretion may prove fatal. When radiotherapeutical treatment is not available a mild interrupted current may be applied by means of electrodes placed over the goitre and at the back of the neck for an hour twice a day.

Complications.—Serious complications may develop in cases of Graves's disease. Thus dangerous crises may be set up by periods of acute hyperthyroidism during which the rapid increase of thyroxin and possibly of other hormones in the blood may cause a marked exacerbation of all the symptoms. In other cases only certain organs react violently to the stimulation. Thus there may be gastro-intestinal crises with intractable vomiting or diarrhœa. Cardiovascular crises may occur with excessive palpitation, greatly increased pulse-rate, and marked restlessness. In all these absolute rest and quiet are essential. Cold may be applied alternately over the goitre and to the præcordium, if the pulse-rate is high, by means of a Leiter's tube or an ice-bag. In gastro-intestinal crises enemata of 5 to 10 oz. of warm water containing a drachm each of sodium bicarbonate and glucose may be given every four hours or run slowly and continuously into the rectum by syphonage from a thermos flask. Half an ounce of pancreatised milk may be given by the mouth every half hour. The vomiting may be controlled by small doses of morphia, given hypodermically or in a suppository, or by the injection of 0·5 c.cm. of pituitrin every 6 or 12 hours. Failing these, 5 gr. of chloral hydrate in a cachet may be given several times in the day. When diarrhœa is a prominent symptom, laudanum may be given with dilute sulphuric acid as required. In the later stages of severe cases of exophthalmic goitre chronic myocarditis with dilatation and hypertrophy of the heart may be present. Under these circumstances there may be auricular fibrillation and gradual cardiac failure. The treatment of this complication is the same as in cardiac failure from other causes, and digitalis or quinidine sulphate may appropriately be employed.

Surgical Treatment.—Although discussion of the surgical treatment does not come within the scope of this article, a brief statement as to the chief indications for operation may be given. In cases of simple hyperthyroidism and in mild cases of Graves's disease no operation is required. In cases of toxic adenoma of the thyroid gland, and in all cases in which signs of pressure on the trachea or recurrent laryngeal nerves are present, operation is required, as cases of toxic adenoma do not as a rule do well under medical treatment, and pressure signs require immediate relief. The selection of suitable cases of Graves's disease for operation is difficult. Cases in which no improvement has taken place after six months' trial of medical treatment, and those in which the goitre is unusually large, are the most suitable for operative treatment by ligation of the thyroid vessels or by partial removal of the goitre. In other cases the physical condition, social position, and wishes of the patient must all be fully considered in the selection of each individual case for operation, for with every care the mortality after operation, though gradually diminishing, is still from 3 to 5 per cent.

GEORGE R. MURRAY, M.D. Camb., F.R.C.P. Lond.,
Professor of Systematic Medicine in the Victoria University of Manchester.

Special Articles.

BRITISH DENTAL ASSOCIATION:

ANNUAL MEETING AT MANCHESTER.

ABOUT 400 dentists are attending the forty-third annual meeting which opened at Manchester in the College of Technology on July 31st, the President being Mr. George G. Campion, of Manchester. It is 31 years since the Association met in this city and the President for the current year is the son of Mr. H. Campion, of Manchester, who was President when the Association last visited the city. The Senior Pro-Vice-Chancellor of the University—Mr. Edward Fiddes—described the growth of the dental school established at the University 39 years ago, and now attended by over 140 students, university training having superseded the former practice of apprenticeship.

President's Address.

The President, in his inaugural address, emphasised the change that had come over dentistry in the last two decades, and congratulated the Association on the fact that their views as to the relation of the State and the dentist had at last received recognition by the Government, and that the Government had at last laid down a skeleton organisation for dealing with this urgent problem of national health and efficiency. It was now known, on the authority of a Government Committee's report, that one-third of all disease in the country was due directly or indirectly to dental disease. Among the general population it was found that the condition of the teeth of women was worse than that of men. In the Western Command from April, 1917, to March, 1918, it was found that between 80 and 90 per cent. of recruits were in need of dental treatment. To avoid the trouble which follows dental disease it was essential to provide from earliest childhood for adequate inspection and treatment, including the practice of cleanliness, the use of a detergent diet, and early conservative dentistry. The State and local authorities had created a nucleus of an organisation for the application of dental knowledge by arranging a dental service in 232 of the 1870 maternity and child welfare clinics now functioning in England and Wales. Other forms of dental service were those of school clinics, tuberculosis clinics, additional benefit under the Health Insurance Act, industrial dental clinics, and the Royal Naval Dental Service and Army Dental Corps. At present—even with the clinics privately organised by a large number of industrial firms—the national service was quite inadequate. School clinics were at present staffed by about 450 dental officers—compared with the school population for England and Wales of about 7 million. For efficient dental work it was calculated that there should be one dental officer for each 5000 children. At present there was not the equivalent of one officer for each 15,000 children. As showing what can be done by the cumulative benefit of treatment over a number of years at a school dental clinic, Cambridge affords a classical example. In 1908, at this clinic only 15 per cent. of the children had sound permanent teeth; the figures in 1920 had been reversed, and the percentage had become 51. Views stated by members of the dental profession ten or more years ago were now proclaimed by the Ministry of Health. Above all the enlightenment of the public on the need for early conservative dentistry must not be relaxed by the Association. The next meeting of the Association will be held in Edinburgh next year, and Mr. J. S. Amoore (Edinburgh) was elected as the succeeding president.

Effects of Diet on the Structure of the Teeth.

At the meeting on August 1st Mrs. May Mellanby spoke on the effects of diet on the structure of the teeth, expounding the researches she had made on behalf of the Medical Research Council on the question of growth of the teeth in dogs. It was proved that the amount of calcium in the diet was not the dominant factor in the calcification of teeth; in this connexion particular importance had to be attached to the content of vitamin A in the diet, which, taken in large amounts, retained and incorporated in the tissues of the body, more especially in the teeth, the calcium salts in the diet. If this vitamin was deficient in the diet, the more cereal was eaten the worse formed were the teeth. Both dentine and enamel were very defective on a diet of oatmeal, but when cod-liver oil rich in vitamin A was added to the oatmeal diet, the dentine and enamel were practically normal. Mrs. Mellanby wished to make it clear that the calcium and phosphorus of the diet do not in themselves control teeth calcification but that their action is subservient to other elements of the diet. The effects of oatmeal on the formation of the teeth raised the question of the excellent teeth of the Highlander at a time when oatmeal formed a large part of his diet. No doubt the calcifying vitamin of herring would play an important part. Milk would also antagonise the action of oatmeal. Thus a diet of milk, eggs, green vegetables, herring, and oatmeal would be expected on the basis of the xperimental results to produce perfectly normal eeth. On the other hand, dietary made up of ereals, and especially oatmeal, together with such ood as vegetable margarine, lard, lean meat, jam, ugar, tea, all substances of widespread consumption n modern dietaries, would be expected to lead to the evelopment of defective teeth and jaws.

Æsthetic Considerations.

Mr. Edward C. Kirk, in a communication on Artistic Harmony in Dentures, expressed regret hat despite the best endeavours of dentists to peruade their clients to accept artificial teeth which were in harmony with the wearer's other features nd expressive of individual character, the public ppeared still to demand the ghastly exhibits of nquestionably false teeth of geometrical evenness nd glittering whiteness, worn indiscriminately by ertain sections of the community, young and old, of oth sexes. The speaker suggested a connexion etween this untoward phenomenon and the superstition, prevalent in some parts of central Europe, that as the milk teeth were shed the child dropped hem into a mouse-hole, the succeeding teeth would e small, white, and even like the teeth of a mouse.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT PORTSMOUTH.

(Continued from p. 233.)

SECTION OF SURGERY.

WEDNESDAY, JULY 25TH.

ON the first day of this section Sir HENRY GRAY, the President, being in the chair, a discussion on the

Treatment of Obstruction of the Colon

was opened by Prof. A. H. BURGESS (Manchester), who based his remarks on the statistics of the Manchester Royal Infirmary during the ten year period 1913–22. During this time out of a total admission of 66,373 cases to the wards, 1278 were for obstruction of the small or large intestine—the term "obstruction" being taken for the purpose of the discussion to include only those cases in which some gross mechanical obstacle was present. Excluding cases of intussusception, the colon was concerned in 199 of the 1278 cases, or 17·87 per cent., the pathological causes of the acute obstruction being distributed as in Table I.

TABLE I.

—	No. of cases.	Deaths.	Percentage mortality.
Malignant growths of colon ..	173	59	34·1
Extracolonic malignant growths	2	0	
Strangulated hernia	9	3	33·3
Adhesions	7	0	
Tuberculous disease of cæcum ..	2	0	
Acute diverticulitis	1	0	
Volvulus	5	2	40·0
Total	199	64	32·2

The table showed the great preponderance of malignant growth as compared with other causes of acute colonic obstruction, constituting nearly 90 per cent. of all cases. During the period under review 485 cases of malignant growth of the large intestine were admitted, 173 of which were associated with acute obstruction, giving a percentage of 35·67. A table was given showing the proportional distribution of these growths with the relative incidence of acute obstruction at each site and the mortality. The figures showed that the rectum was concerned in 46·59 of all growths, but only for 10·98 of those associated with acute obstruction. The sigmoid colon showed a percentage frequency of 29·48 but occurred in 51·44 per cent. of all cases of acute colonic obstruction from malignant growth. The cæcum showed a percentage frequency of 5·15, and a percentage association of obstruction of 6·35. It was also shown that only 13·29 per cent. of the growths causing obstruction were on the right side, as against 86·7 per cent. on the left—a fact not without importance in relation to operative treatment.

The various operations performed for malignant and non-malignant obstruction were included in Table II.

He laid it down as a basic principle of the treatment of acute obstruction of the colon that—contrary to the principle obtaining in the case of the small intestine where it is the operation of choice—resection with immediate restoration of continuity (that is, without drainage of the proximal bowel) is an unjustifiable procedure. In the series under review it was performed 9 times with 3 recoveries (2 of cæcum, 1 of sigmoid) and 6 deaths (1 of transverse colon, 1 of splenic flexure, and 4 of sigmoid)—a mortality of 66·6 per cent., which was almost double the average mortality of the whole series. In the ileo-cæcal region the conditions approximated to those obtaining in the small bowel, and this was the only region of the colon in which primary resection followed by immediate anastomosis might be done. Whenever resection of the colon was essential, as in gangrene from volvulus and internal strangulation, it should be combined with drainage of each end of the bowel, preferably by tying in a Paul's tube; at a later operation continuity might be restored. This two-stage operation was sometimes advocated in acute colonic obstruction from malignant growth, but should, in the speaker's opinion, be restricted to cases in which the colon was grangrenous. In malignant growth it was better to do a cæcostomy for the immediate relief of the obstruction and to follow this up later by a thorough excision of the affected portion of the bowel and its corresponding lymphatic area.

Table II.

—	No. of cases.	Deaths.	Percentage mortality.
A. *Malignant Obstructions*—175 cases (173 growths of colon, 2 extracolonic growths).			
1. Exploratory laparotomy, followed by—			
(*a*) Primary resection ..	9	6	66·6
(*b*) Lateral anastomosis ..	11	3	27·7
(*c*) Cæcostomy	56	18	32·1
(*d*) Colostomy, transverse ..	13	5	38·5
(*e*) Colostomy, sigmoid ..	63	21	33·3
2. Colostomy alone (all sigmoid)	17	5	29·4
3. Cæcostomy alone	5	3	60·0
4. Enterostomy alone.. ..	1	1	100·0
Total	175	62	35·2
B. *Non-Malignant Obstructions.*			
1. Herniotomy..	9	3	33·33
2. Division of adhesions ..	7	0	
3. Ileo-sigmoidostomy for tuberculous cæcum	2	0	
4. Laparotomy and drainage for acute diverticulitis	1	0	
5. Volvulus—			
(*a*) Untwisting alone ..	1	1	100·0
(*b*) Untwisting combined with colostomy	4	1	25·0
Total	24	5	20·8
Total of all cases ..	199	67	33·7

Lateral anastomosis was performed in 11 cases with 3 deaths. In all these cases a preliminary laparotomy had disclosed an inoperable malignant growth and the palliative anastomosis was the alternative to colostomy. In obstruction from growth of the colon a cæco-colostomy should be performed rather than an ileo-colostomy in cases where the ileo-cæcal valve is competent to prevent the regurgitation of cæcal contents into the ileum, an ileo-colostomy entailing in such circumstances, unless combined with either appendicostomy or cæcostomy to prevent tension, a serious risk of gangrene or perforation of the cæcum.

Prof. Burgess then discussed the treatment of acute obstruction of the colon: (1) When it was uncertain whether the obstruction was in the ileum or in the colon; (2) when the obstruction was known to be in the colon but its exact situation was unknown; and (3) when the site of the obstruction in the colon was definitely known.

1. A careful inquiry into the history was useful, the absence of any intestinal troubles prior to the onset of obstruction being in favour of the implication of the small intestine, while pain, diarrhœa, constipation, mucus, with or without blood, in the stools suggested colonic obstruction. The use of the sigmoidoscope and of radiography was scarcely practicable in acute cases, and reliance had to be placed chiefly upon a physical examination of the distended abdomen; its shape, the position of the bulging, the presence of "ladder patterns," as in ileal obstruction, the detection of visible or of palpable peristalsis. Auscultation was also useful to an experienced observer. The "keynote" to the diagnosis was the condition of the cæcum; if this was visibly distended or was felt alternately to harden and soften under the fingers the obstruction was distal to it. When all methods of physical investigation failed, including rectal and vaginal examination, an exploratory laparotomy must be made, preferably through a paramedian incision, splitting the fibres of the lower portion of the right rectus abdominis. When the obstruction was located and its cause found to be an operable growth, the incision could usually be closed and a cæcostomy performed through a "gridiron" incision in the right iliac fossa. Where the growth was inoperable, short-circuiting was indicated where practicable, or failing this a colostomy just above the growth. In the most desperate cases of group (*a*) it was better to make no attempt to find the obstruction, but the cæcum should be exposed under local anæsthesia, and if found distended should immediately be opened ("blind" cæcostomy); if collapsed the first distended coil of ileum presenting should be opened and drained ("blind" enterostomy). In the latter case, should the patient survive further surgical intervention would certainly be called for later on.

2. In cases belonging to this group there was, as the statistics showed, an overwhelming chance that the obstruction was a malignant growth and situated on the left side. In severe cases a "blind" cæcostomy under local anæsthesia was indicated In mild cases, in the absence of any localised tenderness over the cæcum, conservative measures such as repeated enemata, &c., might remove the obstruction, allowing a radical exploration to be made at a later date In the moderately severe cases the choice of preliminary procedure lay between a paramedian exploration and a "blind" cæcostomy. The advantages of the latter were: (1) It could be performed rapidly under local anæsthesia, and with the minimum of shock. (2) There was no interference with the growth and no new adhesions were formed. (3) The cæcostomy opening was as far removed from the area of any further operation as an artificial anus could be. (4) It formed a good safety valve during any subsequent resection operation, giving rest to the sutured bowel and minimising the risk of leakage at the point of suture. (5) When not further required it often closed spontaneously on leaving out the tube, or in any case could readily be sutured. On the other hand, an adequate exploratory operation was always difficult in a distended abdomen, required a general or spinal anæsthetic, and gave information (as to the site and nature of the obstruction) which, however valuable, was not essential at that stage of the proceedings. The speaker was firmly convinced that when in any given case of acute intestinal obstruction the site of obstruction could be located to the colon but was not more precisely known, and where there was no special reason to suspect volvulus or internal strangulation, "blind" cæcostomy should be performed as the sole immediate procedure.

3. In this group in which the actual situation of the colonic obstruction was known, where rectal examination showed the growth to be inoperable on account of local fixation to bladder, prostate, uterus, or sacrum, the operation of choice was a sigmoidostomy, since with a growth so low a future palliative short-circuit was impracticable. Where the growth was determined by rectal palpation to be operable, he preferred a laparotomy through a left paramedian incision, concluding the operation by fixing a loop of the sigmoid into the wound and opening either at once or a few hours later. In cases of palpable abdominal tumour or where obstruction had supervened shortly after a sigmoidoscopic or radioscopic investigation had disclosed its probable site, a cæcostomy was indicated for the immediate relief of obstruction, leaving the field clear for a later exploratory laparotomy, when resection, short-circuit, exclusion, sigmoidostomy, or transverse colostomy might be feasible, in this order of preference. Where none of these was practicable, the incision would be closed and the cæcostomy left as the permanent condition.

In conclusion, Prof. Burgess pointed out that although he had laid stress throughout his paper on what he believed to be the correct principles in the treatment of colonic obstruction once it had developed, yet it was to the earlier recognition of its most frequent cause—malignant growth—prior to the onset of that very serious complication that the attention of surgeons should in the future increasingly be directed.

Mr. **Seymour Barling** (Birmingham) said that there were three points he would wish to make. First with regard to diagnosis, he thought that no one would deny that it was of great advantage to the surgeon if the site of the obstruction were accurately known, and he emphasised the difficulty that this presented in so many cases. He therefore put before the meeting a new method of diagnosis, which he had recently used in three cases of acute intestinal obstruction. Provided that the patient was in a sufficiently fit condition to be able to stand upright for five seconds there was no contra-indication to the method. The patient was taken to the X ray room and screened in the upright position. In his case the intestine above the obstruction showed out very distinctly, and in one case in which the sigmoid was the seat of an annular carcinoma a horseshoe area of gas was seen with pools of fluid at each end, one in the cæcum and one just above the growth. He suggested that this procedure was of great value, and enabled one to relieve the obstruction with one's eyes open, and without any need for exploring the abdomen. Secondly, he wished to remind the section once again of the very poor operative risks most cases of acute intestinal obstruction were. He was sure that they had all had those distressing cases of collapse after quite small procedures. Therefore he urged that a cæcostomy done under a local anæsthesia was the operation of choice, and gave the lowest immediate mortality. Lastly, though an advocate of the cæcostomy, yet he realised some of its disadvantages, amongst them being the undoubted fact that it did not empty the distal part of the colon, and did not obtain that collapsed and empty colon that surgeons wished to see at the line of resection. He thought that the advocates of a blind cæcostomy must face the possibility of a second drainage operation prior to the main attack on the growth.

Mr. ARTHUR MITCHELL (Belfast) felt that he must take exception to Mr. Seymour Barling's remark that quite small procedures produce sudden and severe collapse. He thought that any exploration in cases of acute intestinal obstruction was very dangerous. It required extreme gentleness and absence of exposure, for the distended gut was very easily contused by the hand in the peritoneal cavity, and such contusions only added to the causes giving rise to toxic absorption. He was quite in accord that the easiest, safest, and more rapid method of relieving the obstruction was the correct thing to do, and he agreed that a blind cæcostomy fulfilled these conditions. At the same time he agreed that a cæcostomy did not always completely drain the obstructed colon, but it did abolish absorption of toxic contents. He was interested in Prof. Burgess's figures concerning lateral anastomosis, and was of opinion that this procedure might be more often used with advantage in inoperable cases. He considered that when a permanent colostomy was to be performed the most important consideration was the comfort of the patient, and in this connexion he strongly advised that the distal end should be completely divided, closed, and dropped back into the peritoneal cavity, and the proximal end sutured to the wound. He entered a plea for earlier diagnosis, and emphasised the great importance of diarrhœa as an early symptom. In conclusion, he quoted a case of a man aged 72 with acute obstruction of the sigmoid, in which the cause was a syphilitic infiltration and which was cured by antisyphilitic treatment.

Mr. HERBERT CARSON (London) said that he had had 79 cases of this kind in the large intestine, of these two were due to diverticulitis, five to ileo-cæcal tuberculosis, and 72 to carcinoma. Of these 45 per cent. had had acute intestinal obstruction, the site of which was mainly on the left side. Up to three years ago, only 35 per cent. were operable, but in the last three years the proportion had risen to 52 per cent. He wished to state emphatically that these cases should never be allowed to become obstructed, and that a great need existed for educating students and the general public in the premonitory symptoms. He recognised three clinical types of obstruction of the colon : 1. Partial obstruction, in which symptoms called early attention to the diagnosis, and in which a carefully planned radical attack on the growth was possible. 2. Chronic obstruction which had become acute, in which it was permissible to temporise, and treat with enemata and aperients, keeping a strict guard on the condition of the cæcum. These cases might thus be converted into group 1 cases. If necessary, the cæcum acting as the guide, a drainage operation might become necessary. 3. Acute obstruction the first sign. In these no single stage operation was ever possible, except with growths at the ileo-cæcal valve. He confessed that he was not yet convinced of the advantage of blind cæcostomy, and in his opinion there were the following disadvantages : cases of intussusception with the lump in the left side were unsuitable, a volvulus was not affected at all by a cæcostomy, cases of double obstruction in which the small intestine was involved secondarily to the large were not relieved, and lastly, in inoperable cases a cæcostomy might be a most unsuitable permanent condition, and yet some cases would not stand another operation. But he was a firm believer in a cæcostomy as a step in the technique of every resection. He also pleaded for the avoidance of long blind ends.

Mr. P. LOCKHART-MUMMERY (London) congratulated Prof. Burgess on his excellent paper. He pointed out that the mortality from operations for acute intestinal obstruction was 32 per cent., and that this, though comparing favourably with the figures from hospitals dealing with large industrial areas, was far too high, for we could not face a one in three death-rate with equanimity. He considered that this mortality could be greatly improved by performing blind cæcostomy and postponing the exploration till a later time. The other important factor was the use of local or regional anæsthesia, for he believed that inhalation anæsthesia should never be used in these cases. Mr. Lockhart-Mummery said that not only did he not do a blind cæcostomy on every case of acute colonic obstruction, but he made a practice of performing it as part of any operation which involved division of the colon. He had found that the mortality of colectomy had fallen considerably since the adoption of this procedure. The method of performing cæcostomy was the one he had described in THE LANCET, 1922, ii., 1117. He again stressed the importance of performing this operation under local anæsthesia.

Prof. C. A. PANNETT (London) said that he thought it was by no means easy to be certain that the obstruction in any given case was of the small or the large intestine, for these patients were usually toxic, often in great pain, and frequently unable to give a lucid history. He was personally against a blind cæcostomy unless he was sure of the large bowel being the seat of the obstruction. He quoted 47 cases of acute intestinal obstruction of the colon at St. Mary's Hospital; all had been explored at the time of the drainage operation. Of these one had died, and he felt that the dangers resulting from a further exploration were greatly over-estimated. Of these 47 cases only one-third were operable, and of the remaining two-thirds just over one-half could not be short-circuited. It seemed reasonable to him to ask the advocates of a blind cæcostomy why these people should have two colic fistulæ instead of one. When a blind cæcostomy had been done, he felt that every effort should be made to localise the growth prior to the main attack on it, and in this connexion he mentioned the fact that barium enemata were occasionally very misleading, and he showed four lantern slides illustrating X ray plates in which the barium had got past the stricture and filled the gut above.

Mr. GEARY GRANT (Cardiff) said that in his opinion a cæcostomy with a tightly distended œdematous and friable cæcum was not so easy as some would have us believe, and he was in favour of a colostomy.

Mr. C. P. CHILDE (Portsmouth) thought that in this question it was most desirable to exercise sound judgment and not to be bound by any hard-and-fast rules. He felt that it was self-evident that very severely toxic cases could only be dealt with satisfactorily by a blind cæcostomy, but he was convinced that early cases could be explored without any immediate ill-results following.

Mr. R. D. Mothersole (Bolton), speaking from the point of view of the general practitioner, said that he thought a colostomy had much to recommend it over a cæcostomy.

Mr. M. Mamourian (Ashton-under-Lyne) said that the procedure was governed by the patient's condition. When he found a cæcostomy necessary he used a Murphy's button.

Prof. Burgess, in concluding the discussion, said that he was convinced that blind cæcostomy was the right thing to do. He quite agreed that perhaps one or two cases of volvuli or gangrenous intestine in 100 might be missed, but what was that if the mortality were reduced from over 30 per cent. to under 10 per cent.

A short paper on the question

Are the Results of the Operative Treatment of Malignant Disease Better than Twenty Years Ago?

was read by Mr. Herbert J. Paterson (London), who pointed out that although there was no doubt that during the past quarter of a century surgical technique had greatly improved, and that many of the risks of operation had been materially lessened in spite of the fact that operations practised for malignant disease had become more extensive and radical, there was no convincing evidence that the proportion of ultimate successes was greater than was the case 20 years ago. The returns of the Registrar-General showed an increase in deaths from cancer, amounting to nearly 30 per cent. in the year 1921 as compared with the year 1900, and it was difficult to ascribe this increase entirely to the heightened incidence of cancer and to more accurate death certification. A review of post-operative statistics showed that the percentage of cases free from recurrence after 3 to 5 years was much the same now as it was 25 years ago, and this was true even where mammary cancer was concerned, in operations for which 20 years ago the axilla was not cleared out as a routine measure but only where there was evidence that the glands were involved. In connexion with this apparent lack of progress he would suggest the possibility that the teaching of pathology had been allowed to override clinical experience—e.g., cancer cells had been shown microscopically to be scattered far beyond the macroscopic limits of a growth, and therefore a wide and extensive excision was advocated—whereas clinical experience had shown that operations in which the margin of the growth was very close to the line of resection were sometimes followed by a long interval of immunity, a fact which suggested that the tissues could and often did destroy the isolated cells which were left behind beyond the line of excision. The efforts of modern surgeons had been directed towards more extensive operations, whereas earlier diagnosis and earlier operation should have been their aim.

Mr. Paterson also suggested that in modern surgery the lymphatic glands were attacked too ruthlessly, and that the part played by these glands in the defensive mechanism of the body was scarcely sufficiently appreciated. He recalled Crile's statement that remote visceral metastases were found in less than 1 per cent. of the cases of cancer of the head, face, and neck, and that the disease was almost invariably limited to the extensive collar of lymphatics surrounding the neck; but whereas Crile looked upon this fact as a clear indication of the necessity for the removal en bloc of these glands, the speaker believed this inference to be illogical, and urged that the barrier of glands should be left for several weeks after the removal of the primary growth. He had operated upon eight cases of carcinoma of the tongue by this method, one of whom died of broncho-pneumonia seven days after the operation, one died 15 months after the operation, one was untraced, and was assumed to be dead, while the remaining five were alive and well, four of them more than six years after the original operation. For the past three years he had adopted a similar method in dealing with cancer of the breast, but it was too early to judge of results. He submitted that there was solid justification for an extended trial of this procedure of operation in two stages whenever practicable—i.e., removal of the growth, followed at a later period by removal of the glands. He concluded by emphasising the necessity for a vigorous campaign to impress on the public the supreme importance of early recognition of the disease, and of early operation, which, so far as their present knowledge went, offered the only hope of cure.

THURSDAY, JULY 26TH.

On the second day, Sir Henry Gray (Aberdeen) again being in the chair, Mr. D. P. D. Wilkie (Edinburgh) opened a discussion on the

Treatment of Acute Primary Infections of the Hand,

including sequelæ. Mr. Wilkie began by pointing out the great importance of the subject both from a medical and from an economic standpoint, touching as it did the wide problems of infection, resistance, and immunity. He deprecated the tendency in hospital practice to look upon infections of the hand as belonging to the realm of minor surgery to be dealt with by the less experienced members of the staff, whereas not only did no class of case present more difficult problems, but also upon the line of treatment adopted the very life of the patient might depend. In discussing the subject there were certain fundamental pathological considerations that had to be borne in mind. The introduction of pathogenic micro-organisms into the tissues was followed by well-defined general and local tissue changes; but although these reactions were essentially protective in function, in the hand the outpouring of lymph and the local aggregation of phagocytes might, in areas in which space was limited, cause a high degree of tension, endangering the vascular supply and the vitality of the part. In addition to this, the concentrated toxins of the infecting bacteria, together with the proteolytic ferment liberated from the dead and dying phagocytes, tended to produce the death and liquefaction of the neighbouring tissue cells, and from such an area there would inevitably be a deleterious absorption of bacterial toxins and proteoses. The aim of surgical intervention was to provide for the drainage of such areas of suppuration and tension before the occurrence of irreparable damage; and in this connexion it was well to bear in mind that the disability following even an unnecessarily extensive incision was negligible in comparison with that resulting from a burrowing, liquefying, and prolonged suppuration followed by the inevitable fibrosis, fixing tendons and muscles, stiffening joints and compressing nerves and blood-vessels. The preservation of tissue without function was a mere waste of time and energy.

Anatomical Considerations.—There were three points in the anatomy of the hand that had an important bearing on the spread of infection in this region. (*a*) The extensive network of lymphatic vessels in the hand, especially on its palmar aspect. (*b*) The division of the cellular tissue into spaces. In the pulp of the fingers dense fibrous septa, extending down to the periosteum of the phalanx, enclosed the fatty tissue, infection of this tissue leading to great tension, with necrosis which was very apt to involve the bone. In the palm of the hand the two most important of the deep cellular spaces were the middle palmar and the thenar spaces. A collection of pus in the middle palmar space tended to point along the lumbrical muscles of the third, fourth, and fifth fingers; and in the thenar space it tended to point at the radial side of the index finger. A knowledge of the existence and boundaries of these spaces was essential for the early recognition and drainage of a collection of pus in either situation. (*c*) The anatomical arrangements of the tendon sheaths, owing to which any accumulation in them under tension was apt to rupture either into one of the palmar spaces or into the deep cellular planes of the forearm underneath the flexor communis digitorum, with the frequent sequel of infection of the first interphalangeal joints.

Types of Infection.—These were two: lymphatic and suppurative. In the lymphatic type the infecting organism was almost invariably the streptococcus, and the danger of septicæmia was a very real one. It was vital that a correct diagnosis should be made, as the treatment of such cases differed fundamentally from that of suppurating whitlow. The suppurative type occurred either as a cellulitis, or as a tendon-sheath infection, the former occurring mainly either in the tip of the finger or deep in the palm of the hand, and the latter either as a primary infection of the sheath from a direct wound, or as a complication of a lymphatic infection of a finger. The essential features of tendon-sheath infection were the early development of tension owing to the limited capacity for expansion possessed by the sheath, and the precarious nutrition of the structures within the sheath. A complication which may follow either of these types of infection—cellular or tendon sheath—was infection of the phalanges and interphalangeal joints.

Diagnosis.—The first essential in diagnosis was to decide which type of infection was present. In acute lymphatic infection there was marked constitutional disturbance, slight local swelling, swelling of the axillary glands, and red lines up the arms. In the suppurative type there was either (*a*) a localised swelling at the tip of the finger with tense and tender pulp, or (*b*) a slight prominence of the palm and marked œdema of the dorsum of the hand, with or without a swelling in the cleft between the fingers, or (*c*) a uniform swelling of the finger, flexed position, pain on passive extension and tenderness on pressure over the proximal part of palmar aspect of the finger, or (*d*) a combination of these according to whether or not the tendon sheaths were infected.

Treatment.—Great emphasis was laid upon the importance of prophylaxis in the shape of prompt antiseptic dressing of all wounds, especially in centres of organised industry. Where infection was already present the following principles were to be borne in mind: 1. The necessity for working with and not against Nature in her efforts to localise and limit the spread of infection. 2. The necessity for incising at the earliest possible moment where pus had accumulated under tension. 3. The necessity for making large incisions allowing of free drainage where spreading suppuration was present. 4. The importance of rest to an inflamed part. 5. The necessity for exercising the minimum of interference with the functional capacity of the hand compatible with the arrest and localisation of the infection. During the early stages of acute lymphatic infection no incision was ever to be made. The principles of treatment n these cases were to diminish absorption, to aid local resistance, to combat toxæmia, and, where possible, to give passive immunity. Bier's passive hyperæmia was probably the most valuable therapeutic measure n the acute lymphatic type, other auxiliary remedies being the giving of fluid in large quantities by mouth or rectum, and the subcutaneous injection of arge doses (50 c.cm.) of polyvalent antistreptococcic serum.

In suppurative cellulitis early incision with free drainage was always indicated. Two lateral incisions n the finger pulp would completely relieve tension, and, if made in time, would save the phalanx from necrosis. For deep suppuration in the palm it was necessary to make an incision in a cleft between two ingers and to thrust a sinus forceps in along a lumbrical anal. For suppuration in the thenar space, through-and-through drainage of the first interosseous space was essential. In the treatment of nail-fold infections where the pus had already made its way out under the old, the essential for rapid healing was to pack in trands of gauze between the nail and the fold with he blunt end of a straight sewing needle. In infective eno-synovitis free incision at the earliest possible moment under a general anæsthetic was necessary, a tourniquet in the shape of an Esmarch's bandage to the upper arm being advisable. It was a good rule to make all incisions sufficiently free to obviate the use of drainage-tubes, and so to limit the subsequent fibrosis. The after-treatment included moist dressings and hot saline baths until the subsidence of the acute inflammation. In cellulitis rest should be the rule until there was definite localisation of the infection, after which movement was to be encouraged. In tendon-sheath infections movements, active and passive, were indicated at as early a stage as possible, delay in instituting appropriate exercises endangering the ultimate utility of the hand.

Mr. C. M. **Page** (London) emphasised the importance of the subject from an economic aspect, and insisted that all such patients should be treated as in-patients and not as out-patients. He criticised Wilkie's classification in that lymphatic infections may be more or less chronic, and he preferred to call the severe cases fulminating streptococcal infections. He agreed that in these cases incisions were quite wrong and did a great deal of harm. In other types of infection the main object was to relieve tension by affording an outlet to the pus, and he did not consider the opening up of spaces by forceps advisable, as by this procedure tissues were often infected. The after-dressings were important, and he preferred dry gauze or paraffin gauze to wet dressings. With regard to the restoration of function in these hands, he found that if tendons had sloughed away plastic surgery offered very little hope of success in obtaining functioning tendons, but if the tendons were intact much could be done. He deprecated the common custom of treating these hands on a straight splint, for if adhesions formed it became impossible to get flexion of the fingers. They should always be treated half-way between flexion and extension, and then later full flexion could be obtained, either by graduated extension splinting or by breaking down the adhesions under an anæsthetic. He had found the paraffin bath very useful in the after-treatment of these cases, but he could not explain the rationale of the treatment.

Mr. F. D. **Saner** (London) thought that not sufficient attention was paid to prophylaxis of hand and finger infections, and he felt that it might be advisable to recommend immediate excision of all wounds and pinpricks. Whenever the patient had the premonitory symptoms the infection had already gained a foothold, and in such cases without actual pus formation he preferred large hot fomentations; and not until grave constitutional symptoms had supervened did he advise incision. He then called attention to the dilemma often confronting surgeons in the condition of the axillary glands. The problem of deciding on the necessity for incising axillary glands was a very difficult one; on the one hand, they formed an important line of defence; on the other hand, if suppurating, they must be opened. He believed that complete immobilisation of the whole limb was a very essential part of the treatment. The formation of pus was to be noted with relief, for pus was an indication of defence, and unless under tension was of no moment. He was not in favour of tubes or packs in his incisions, but he preferred to excise an ellipse of skin and fatty subcutaneous tissue so that drainage was not impeded.

Mr. J. E. H. **Roberts** (London) said that he would confine himself to the infections of the pulp of the finger in the distal part. He showed that in front of the distal phalanx there was a more or less closed area of loose fatty tissue, down to which ducts of glands reached, the gland often lying in this space. Infections of this part of the finger frequently arrived via the ducts without any prick or injury. The arrangement of the vessels was of great importance, for the artery traversed the space, and the blood-supply to the distal phalanx was arranged in this way. The artery supplying the base of the distal phalanx was given off before the artery entered the space, but those going to the shaft and extremity were given off in the space. This explained why it was that the shaft so often necrosed while the articular end survived. The incision he advised was one which completely opened the space; it was horseshoe-shaped, beginning on one lateral aspect, passing across the tip, and ending on the other lateral aspect. The flap so formed was turned down, and a strip of rubber tissue inserted and the flap replaced. Drainage was rapid and healing perfect. In those cases of acute fulminating streptococcal infections he was not enamoured of hot fomentations, but preferred hot baths for the hand and arm. In cases where the arm became swollen and painful, he thought that a linseed poultice was a very excellent application. In acute teno-synovitis he was entirely opposed to anterior median incisions, and strongly advocated lateral cuts. With regard to the after-treatment, he used hot fomentations for 48 hours, and then used paraffin and flavine dressings. In his opinion there was a widespread tendency to dress too frequently. Early movements were essential, and he agreed with Mr. Max Page that the correct position was one of semi-flexion.

Mr. R. M. HANDFIELD-JONES (London) confined himself to the discussion of the infection of two fascial spaces in the hand occurring as complications in the course of infections of the fingers, these spaces being the middle palmar space and the thenar space. After describing the boundaries and the relations of these spaces he enumerated the avenues of infection.

(*a*) *Middle Palmar Space.*—This might be infected in one of eight ways: from little finger tendon sheath (if not in continuity); from ring finger tendon sheath; from middle finger tendon sheath; from lumbrical canal of little, ring, or middle finger; from rupture of ulnar bursa; from direct puncture wounds; by lymphatic spread; from thenar space.

(*b*) *Thenar Space.*—This might be infected by: index tendon sheath; flexor longus pollicis sheath; middle tendon sheath (occasionally); index lumbrical canal; rupture of radial bursa; direct puncture wounds; lymphatic spread; middle palmar space.

The diagnosis was obviously of great importance, for if left untreated the infection would spread in almost every direction except towards the surface. General symptoms were those common to all severe infections. Local symptoms included: (1) Pain, limited to the area of the space involved. (2) Marked tenderness over the area concerned. (3) Swelling, the location and degree of which was the most helpful point in the diagnosis. In the thenar area where there was no dense fascia the thenar eminence became ballooned out; but in the middle palmar space the dense fascia prevented anything like the same degree of distension, although it was enough to obliterate the normal cavity of the palm. Swelling on the dorsum of the hand was a point of great importance. Every infection in the palm caused swelling of the dorsum, the inflammatory process travelling via the lumbrical canals. Except in direct infections of the back of the hand primary dorsal abscesses were extremely rare. This was an important point to remember, because frequently the dorsal swelling appeared to the untrained eye to be the most prominent feature of the case, repeated incisions being made without any improvement whatever to the hand. In 99 per cent. of cases no incision should be made on the dorsum at all, unless to open the thenar space. (4) Position and movement of the fingers which tended to be semi-flexed but could be moved without pain, thus differentiating the condition from an acute teno-synovitis. Treatment consisted of opening and draining the spaces. The middle palmar space was drained by an incision along one of the three lumbrical canals, the canal most obviously affected being chosen, the tendons exposed, and a pair of artery forceps thrust under them, following the lumbrical muscle. The thenar space was opened by an incision on the dorsum on the radial side of the index metacarpal. The after-treatment consisted of hot dressings for 36–48 hours, followed later by dry dressings with the hand immersed in a radiant heat bath for a period of one hour twice in the 24 hours, and a very early institution of movements of fingers, hand, and wrist.

Mr. G. T. MULLALLY (London) spoke entirely of whitlows of the fingers. He said that anatomically the fingers might be regarded as being composed of three compartments, for the flexion creases of the fingers coincided with fibrous tissue thickenings. In the presence of inflammatory swelling these fibrous thickenings were sufficiently rigid to act as a band strangulating the vessels, and he brought forward the view that the pathology was analogous to that of a strangulated hernia, first the veins being constricted, giving rise to swelling, throbbing and tension, and secondly, the artery being occluded, and necrosis followed. For this reason he was of the opinion that any incision planned to relieve tension in a finger should pass across the next proximal flexion crease to do away with the constriction band. He was still convinced that lateral incisions had no advantages over the anterior median incision which he always practised.

The PRESIDENT said that the surgery of the war had taught many lessons that were applicable to this subject. He thought that of prime importance was the properly placed incision at the earliest opportunity, and he felt very strongly that Willem's mobilisation treatment of infected joints was strongly indicated in septic fingers. Early active movements should be encouraged and maintained. He was convinced that in these cases there was too much splinting and much bad splinting.

Mr. HAROLD BURROWS (Portsmouth) said that he had been worried by septic phlebitis on more than one occasion, and that such complications as metastatic abscesses in hip and knee-joints, &c., were evidence of the presence of a septic thrombosis. He dressed his wounds with a paraffin-flavine dressing.

Mr. M. MAMOURIAN (Ashton-under-Lyne) drew attention to the ugly deformity which resulted after the loss of the greater part of the terminal phalanx, and emphasised the fact that women greatly objected to such an unsightly finger. He was in the habit of inserting an ivory peg exactly the same length as the sequestrated phalanx in such a way that it rested on the base of the phalanx, and was held in position by the flaps of skin being sutured over it. This was a sufficient support to prevent shortening of the flaps until the new bone had regenerated. In the case of the thumb in working men, he advised the insertion of a bone graft, rather than amputation which was the only alternative in certain cases.

Mr. WILKIE briefly replied.

Mr. A. MCCONNELL (Dublin) read a short paper on

Ventriculography,

giving his experiences in certain cases in which he had practised the operation as originally described in America by Dendy. The operation was performed under local anæsthesia, two areas of the skull being exposed. The first site (A), to be used for the injection, was 1¼ inches behind the external auditory meatus, and 1¼ inches above Reid's base line; the second site (B), to clamp the apparatus in position was 1¼ inches behind the external auditory meatus and 2½ inches above Reid's base line. At A the skull was exposed, and a small trephine hole made down to the dura mater; at B only the outer table of the skull was removed in a small circle. A semicircular bar connected the drill end at A, and the pin-holder at B. The pin was screwed tight to the skull, and the whole apparatus then closely applied so as not to shift. At A a perforated metal ball fitted closely to the trephine hole, and through its perforation the cannula was inserted in a straight line with B. The apparatus being thus firmly attached to the head, the patient was removed to the X ray department, and the injection proper begun. Great care was taken that the amount of gas injected was exactly equal to the amount of cerebro-spinal fluid removed. This was done by using a syringe with a two-way tap, sucking out cerebro-spinal fluid first and then injecting oxygen. Mr. McConnell showed excellent radiograms illustrating his results. In all he had performed ventriculography upon 14 cases. Of these five gave no result, and nine gave positive results of internal hydrocephalus, or deformities of the ventricular shadow from tumours,

&c. In two cases out of the 14, sudden death had occurred within 24 hours. In each case the patients appeared well, but suddenly sat up and fell back dead.

FRIDAY, JULY 27TH.

The third day was given up to a discussion on

Anæsthetics from the Surgeon's Point of View

in which both surgeons and anæsthetists took part. The opening paper was contributed by Mr. **WILFRED TROTTER**, who began by emphasising the necessity for a close and sympathetic understanding between the surgeon and the anæsthetist in order to secure for the patient the full advantages of modern surgery. He pointed out that since many of the most valuable methods of inducing anæsthesia at the present day—such as the various regional and infiltration methods—were definite surgical procedures in themselves there would probably be in the future a closer approximation of the training of the anæsthetist to that of the surgeon, and a more complete assimilation of the anæsthetist into the surgical team. Such an assimilation would probably go far towards solving some of the difficulties that arose in the relation between anæsthetist and surgeon in operations such as those on the face, pharynx, and upper air passages.

It was clear that in spite of the great progress that had been made within recent years in the subject of anæsthesia there was still no single method capable of general application to all cases. In every individual case the choice of an anæsthetic had to be made from a large number of possibilities, this choice frequently nvolving very careful consideration. He proposed o discuss in his paper only the methods with which he was himself familiar, classifying them in the three groups of inhalation methods, regional methods, and ocal methods.

1. *Inhalation Methods.*—(*a*) *Ether* was the nearest approach to an anæsthetic of general use, but with all its advantages it had many drawbacks considered rom the broad view of the patient's interests. These drawbacks included the over-stimulating effect of the drug on the circulatory and respiratory activities of he patient, adding seriously to the exhausting effect of the operation. It was irritating to the respiratory organs and to the stomach, leading frequently in the mmediately post-operative period to coughing and vomiting; and since the most absolute repose was ndicated for at least 24 hours after all serious operaions, a liability to cause post-operative vomiting hould be looked upon as a grave disadvantage in any næsthetic method. Ether was also contra-indicated n very severe or long operations which were apt to be followed by much shock. Its advantages were, ase of administration, immediate safety, and proundity of anæsthesia. (*b*) *Chloroform.* The numerous isadvantages of this drug included its immediate anger, the relative lack of depth in the anæsthesia produced, its irritant effects on respiratory and gastric mucous membranes, and its capacity for producing the o-called delayed chloroform poisoning. Chloroform was absolutely inadmissible in infants and children in ll circumstances; it should not be used for robust nd young or middle-aged adults unless specially ndicated; nor should it be used for trivial operations r "casual" anæsthetics. Chloroform was also ontra-indicated in young people suffering from acute r chronic infections, in patients suffering from malutrition or starvation, and in diabetics. In spite of ll these disadvantages and contra-indications, hower, chloroform was valuable and, indeed, indispensble in certain fields. It produced a smooth and placid næsthesia; it was useful in cases where any increased urgescence in the respiratory tract was to be depreated; and it was almost absolutely safe when given hrough a laryngotomy or tracheotomy opening. lthough chloroform was not usually admissible in erious abdominal work, it had a great field of usefulness n operations on the mouth, jaw, larynx, and pharynx, nd in his own practice this was the anæsthetic nployed in all such cases, almost invariably in combination with laryngotomy or tracheotomy. Chloroform was also valuable in many brain and spine operations and for the radical operation for carcinoma of the breast. (*c*) *Nitrous oxide* was incapable of producing a deep anæsthesia in any but delicate or enfeebled patients unless it was supplemented by local or regional anæsthetisation of the part to be operated upon, its efficacy being also increased by preliminary hypodermic injections of morphine.

2. *Regional Methods.*—(*a*) *Spinal anæsthesia* was unsuited to enfeebled patients and to those with acute and serious abdominal conditions. Its special indications were in operations on the lower limbs, perineum, pelvis, and lower abdomen where shock was to be feared; where metabolic disturbances were to be avoided, as in diabetes; and where full abdominal relaxation was essential. Spinal anæsthesia should generally be preceded by narcotic drugs and might usefully be combined with the use of nitrous oxide. (*b*) *Sacral anæsthesia*, in combination with narcotics, was valuable in operations on the perineum, and was specially indicated in operations for piles. (*c*) *Nerve tissue anæsthesia.* Two special forms of this were in common use; the blocking of the intercostal nerves for operations upon chest and abdomen, and blocking of the brachial plexus above the clavicle for operations on the arm. The complementary use of narcotics and possibly of nitrous oxide should always be considered.

3. *Local Methods—Infiltration Anæsthesia.*—The two chief spheres of usefulness for this method were (*a*) in such conditions as superficial, definitely limited dissections, in radical cure of hernia, especially inguinal and umbilical, and in excisions of the testicle; and (*b*) as a special procedure where other methods were urgently contra-indicated. In the hands of the expert it was capable of application to almost any surgical operation save where diffuse infective conditions were present. The main factors for its successful employment included the preliminary use of narcotics, the injection of an abundance of solution, and allowing full time for its action.

Sir **W. I. DE COURCY WHEELER** (Dublin) said that he would have entitled this discussion, "The Anæsthetist and the Surgeon." He was sure that in the minds of all present the picture was vividly present of an emergency abdominal operation with an inefficient anæsthetist—the rigid muscles, the protruded intestines, the harassed surgeon. He did not suggest that the surgeon was always free of blame, for not all surgeons were gentle, and a ruthless hand under the diaphragm could upset any anæsthetised patient, and again, some surgeons were invariably in too great a hurry to begin. Many things went to make a really successful anæsthesia—viz., a consideration of the nature of the operation, the type of patient, the temperament of the surgeon, and a sound judgment throughout. He asked to make three points especially. First there was the patient who, without any obvious cause, collapsed, stopped breathing, and gave all concerned many anxious moments. In these cases the abdomen was usually opened and perhaps an investigation just commenced. Artificial respiration usually had to be resorted to. He wished to stress the fact that all the ordinary methods could not, and should not, be applied. He advocated very strongly a return to the old direct method, by blowing into the patient's lungs. This should be done rhythmically once every four seconds, and very rarely failed. He quoted the classical early example of direct artificial respiration—viz., Elisha and the widow's son. Secondly, he thought that chest complications ought not to be laid at the door of the anæsthetist, for he thought that the rigidity of the diaphragm had much to do with the onset of so-called ether bronchitis and ether pneumonia. He recalled that the late J. B. Murphy had drawn attention to the incidence of acute pulmonary œdema as a complication of operations for large hernias, &c., and had ascribed it to the want of descent of the diaphragm. In many upper abdominal lesions (especially acute ones) the diaphragm was held rigid just as the recti were, and for this reason in doubtful cases he thought that the presence of crepitations at the base of a lung was an indication that the condition was an abdominal one rather than a pulmonary. Lastly, he said that for 20 years he had been in the habit of combining local anæsthesia with general, for the abdominal relaxation obtained was far superior and less general anæsthetic was required. He ended by expressing his complete detestation for chloroform.

Dr. A. L. **Flemming** (Bristol) referred to the somewhat prevalent habit of mutual recriminations that occurred between surgeon and anæsthetist, and he was pleasantly surprised that at this meeting he was not called upon to retaliate in kind. But he was quite certain that there was a very great need for a much closer contact between the surgeon and the anæsthetist. Many points arose which could be settled by consultation, but in so many cases the two seemed poles apart and no combined effort was obtained. He was of the opinion that ether was the most satisfactory anæsthetic if the surgery was gentle, rapid, and dry. He considered that the administration of local anæsthetics by anæsthetists was absolutely useless unless a complete accord existed between them and the surgeon. What was the good, he asked, of an anæsthetist inducing a perfect local anæsthesia for the proposed operation, if the surgeon regarded the patient somewhat in the way that the pathologist does a body awaiting a post-mortem examination? He wished to lay stress upon the fact that the teaching of anæsthetics needed great revision, and should be markedly improved.

Dr. A. E. **Boyd** (Dublin) confined himself almost entirely to colonic anæsthesia. He said that the bad results in this country were due to the use of too high a percentage of ether in the ether oil mixture. He followed Gwathmey's technique very closely except for the mixture. For many months he had used a 50 per cent. ether oil mixture and had had no evil effects. He found it quite safe, very easily controlled, and was followed after operation by a dreamy analgesia. A careful preparation was needed, and consisted of an enema the night before and a rectal irrigation the next morning. The amount to be used must be carefully checked. Of the 50 per cent. mixture he used 1 oz. for each 20 lb. body-weight of the patient. He gave $\frac{1}{6}$ or $\frac{1}{4}$ gr. morphia half an hour before the injection, which had to be given slowly. At least 15 or 20 minutes was necessary for the introduction of the mixture. This mixture did not produce surgical anæsthesia, and here the control came in, for the balance was just tipped over on to the side of surgical anæsthesia by small amounts inhaled from a mask. The period over which the absorption from the large bowel lasted was one and a half hours, so that longer procedures would require rather more inhalation at the end. When the patient returned to bed the colon was washed out, and 2 oz. of olive oil injected. He considered that all head, neck, and breast operations should be done by this method. He also mentioned that all his diathermy cases of the tongue, tonsil, and mouth were done by this anæsthetic.

Mr. A. **McConnell** (Dublin) said that colonic anæsthesia as described by Mr. Boyd was the best he had known, and he did all his operations upon the neck, brain, breasts, and diathermy by this method.

Mr. **Cuthbert** (Gloucester) favoured local anæsthesia for all head cases.

Mrs. **Dickinson Berry** (London) thought that ether anæsthesia if kept light did not produce an undue stimulation, but rather just enough to stand the patient in good stead. She was greatly in favour of combining local anæsthetics with a slight general administration.

Dr. **Basil Hall** (Bradford) said that he was all in favour of simplicity in the administration of anæsthetics, and he mistrusted all the modern apparatus with complicated machinery. No hard-and-fast rules were possible, nor was any apparatus of the least value which dealt only with fixed percentages. What he personally wanted was an anæsthetist who was able to judge each patient separately and deal with according to the condition found. Half the battle in operative surgery was to establish a team with an intimate knowledge of each other. He thought that anæsthesia was often pushed quite unnecessarily far. His experience of ethanesal has been most satisfactory, and he now preferred it to all others. He emphasised the fact that for the patient by far the worst part of an operation was the anticipation of the anæsthetic.

Sir **Crisp English** (London) had three remarks to make. First, he had tried ethanesal for two years with admirable results, and this July he had arranged with his anæsthetist to go back to ordinary ether for one month as a control. There was no doubt in their minds that ethanesal was superior in every respect. Secondly, he advocated the induction, especially in children, by ethyl chloride. The induction is very rapid, and all the long struggling excitable period was omitted, and he thought that in children this was exceedingly valuable. Lastly, he thought that in the hands of such experts as Mr. Boyle, gas and oxygen was an extremely useful anæsthesia, and there were many cases which were safely dealt with by it which would not stand a more toxic drug.

Prof. C. A. **Pannett** (London) drew attention to a condition of delayed ether shock which was not infrequently seen after ether anæsthesia. He mentioned cases leaving the table in good condition only to be in a condition of severe collapse three hours later. He did not find it possible to acquit the anæsthetist of all responsibility for lung complications, though he liked Sir W. I. de Courcy Wheeler's explanation of such cases. And lastly, and most important, he had been attempting lately at St. Mary's Hospital paravertebral nerve-block anæsthesia with good results. The technique was not yet perfected, but it was being made so; he had already done partial gastrectomies, cholecystectomies, &c., under paravertebral anæsthesia.

Mr. **Trotter** briefly replied.

Mr. **Clifford Morson** (London) read a short paper in which he explained his method of, and reasons for, division of the vasa deferentia in operations upon the prostate.

SECTION OF PUBLIC HEALTH.

Thursday, July 26th.

This section, which met on two days, was presided over first by Dr. A. **Mearns Fraser** (M.O.H., Portsmouth) and then by Dr. **Lockhart Stephens** (M.O.H., Warblington U.D.). A discussion on factors contributing to the

Recent Decrease in Infant Mortality—

Are such factors likely to be permanent or temporary? —was ably opened by Dr. J. **Wheatley** (M.O.H., Salop). His main conclusion was that the fall of the infant mortality-rate had been due chiefly to education. The earlier part of the fall was probably due to the operation of the Education Act of 1870 in increasing the intelligence of the people and the sense of responsibility of parents. One would not expect an immediate effect from the Education Act but rather an effect delayed for about a generation, and that was what had actually happened, the fall having begun in 1900. The latter part of the fall was probably due to the continued effect of better general education, aided by special education influences, brought to bear more particularly on the mothers, such as by child welfare, tuberculosis and school medical inspection schemes, and by the establishment of district nurses.

Dr. Wheatley's paper was illustrated by tables and charts showing infant mortality rates from 1840 onwards, giving the dates of introduction of various measures likely to affect it. The various possible factors were discussed. The fall in the birth-rate began in 1880, but up to 1900 had not improved infant mortality. The same could be said of the improved sanitation which followed the passing of the Public Health Act of 1875 and coincided with a con-iderable fall in the general death-rate. The great icrease in prosperity and in the purchasing power of he wage which took place in the latter part of the ineteenth century had no effect ; in fact, the evidence vent to show that improvement in wages without nprovement in education and standards of conduct esulted on the whole in more drunkenness, a greater arelessness, lessened natural feeding of infants, and consequent increase in infant mortality. From 1840 ɔ 1900 the purchasing power was trebled, with no eduction of infant mortality, while from 1900 to 1913 iere was a slight decline in purchasing power with a ery large reduction in infant mortality.

The removal of slums had been on too small a scale ɔ be an important factor. From 1914 to the present me there had been a cessation of sanitary schemes, marked deterioration of housing, and a lessened ficiency of sanitary administration, accompanied, evertheless, by a very marked diminution of infant iortality. He (Dr. Wheatley) did not wish to belittle ich important matters as the pollution of the air by noke, overcrowding, and bad housing, but these were ily very specially potent when combined with ignor- ace and carelessness, and it was this combination hich caused the high rates in northern industrial ɔwns. He believed with Dr. Brend that air pollution iused an excess of infant mortality, but there had been ɔ improvement in this respect to account for the duction in the latter. He did not think the decline as due to an improved milk-supply, in rural districts any rate, or that the use of dried milk had been ifficiently general to be a large factor.

Ante-natal work was more a thing of the future and id not appreciably affected neo-natal mortality as et. There was no evidence that the improvement was ie to a change in climatic conditions. Between the nsus of 1901 and that of 1911 there was an increase the number of married women industrially employed id the figures for 1921 were not yet published. essened horse traffic and tarred roads meant fewer es and more open windows, and had no doubt been nong the minor contributory factors. As regards the ture, he thought the improvement would be per- anent and progressive. If the fall had been due to ild winters or periodicity of infectious diseases, we ight have real set-backs, but there was nothing inting to this, and apart from temporary set-backs used by epidemics of influenza, measles, whooping- ugh, &c., the improvement, in his opinion, would be ogressive as long as education kept ahead of material lvancement.

In the discussion which followed Dr. H. PECK [.O.H., Chesterfield R.D.) agreed generally with Dr. heatley, but thought privy conversion was one nitary measure which had had an effect. He also stanced the good effect of "Summer Time" and the eaner air during the coal strike. Dr. H. B. BRACKEN- RY (London) was sceptical as to the good results of aternity and child welfare work. He thought the v mortalities in Connaught, mentioned by Dr. heatley, were remarkable, and he suggested the bulation of districts according to their varying nditions. Dr. D. C. KIRKHOPE (M.O.H., Tottenham) ought the education of the mother in her home was e most important form of education and that the rk of the centres was vital. Dr. G. C. TROTTER .O.H., Islington) thought home visitation was *the* ing. It was not only the primary education that d been important but the educative effect of working- ss movements which operated all through life. . J. W. MILLER (M.O.H., Radnorshire) thought ucation by health visitors had been important by couraging breast-feeding. Education in domestic giene in schools was not practical. Education in the mes and by centres was extremely important. . G. HARPER PEARCE (M.O.H., Batley) said smoke d increased as infant mortality decreased. Education the mothers and the use of dried milk had been the ef causes of the decrease. Dr. W. A. BULLOUGH .O.H., Essex) thought the district nurse-midwives d been important educators. Dr. H. SCURFIELD te M.O.H., Sheffield) said the Irish Carnegie report emphasised the freedom of the Connaught mothers from venereal disease and abuse of alcohol. It was also possible that a religion which placed motherhood high had maintained its hold on a population undegraded by the agricultural and industrial revolutions which occurred in England during the reign of George III. He was in general agreement with Dr. Wheatley but attributed more importance to the use of dried milk, and mentioned the opinion of the late Dr. Ewart that the increasing use of a safe milk had been the chief factor. The teaching of housecraft was considered important by many, but always suffered if the Education Committee's estimates had to be cut down. The new midwifery would produce an effect on neo-natal mortality when it got going. Prof. F. E. WYNNE (M.O.H., Sheffield) said an investigation made by him recently showed that most of the Sheffield infant mortality reduction was in diarrhœal diseases. His belief was in the special education of the mothers. The teaching of domestic hygiene in the schools was not a practical form of education.

Dr. WHEATLEY, in replying, said he had limited himself to those factors which, in his opinion, had had a possible effect in causing the decrease in infant mortality. Heredity was obviously not one of these. He could not understand anyone minimising the effect of education. In reply to Dr. Brackenbury he thought the maternity and child welfare schemes had produced a great and immediate effect as contrasted with the delayed effect of improved general education.

Dr. SCURFIELD read a paper on

The Value of Watercress

as a food, and suggestions for its extended use, which evoked considerable interest. In his preliminary remarks Dr. Scurfield drew attention to the proved importance of a vitamin-rich diet not only for laboratory animals but for animals such as pigs, poultry, and dogs kept under ordinary conditions, and the obvious inference that the same held good for human beings if they wanted to be at their best. There was just the danger that people would get sick of the talk about vitamins before they had absorbed the comparatively simple teaching of the newer nutrition—viz., that they needed to include more of the "protective foods"—i.e., milk, green vegetables, and fruits—in their dietaries. Watercress was a green food which had stood the test of time and had a great reputation as a promoter of health. It was certainly, like other cruciferæ, a valuable antiscorbutic. It probably also contained the other two vitamins. He hoped research would be undertaken both as to its chemical and vitamin content. It was a green vegetable, which, like lettuce, was eaten unspoiled by cooking, but which, unlike lettuce, was available all the year round at a moderate price. If there was to be an extended use of it inspection of the sources of supply was desirable. Such inspection would be welcomed by the large growers, who from his experience took great care at the present time with respect to purity of water, &c. In his experience most people, including children, liked it, but many only met it in railway dining cars or as a garnish to chicken, &c., in a restaurant. It was much more used in France, and in his belief its more extended use in this country would be useful in correcting errors in our dietaries due to urbanisation.

FRIDAY, JULY 27TH.

The second day's proceedings opened with a discussion on the

Effect on Health of Sewer Air and Drain Air,

introduced in an interesting paper by Prof. WYNNE, the gist of whose paper was to the effect that the theory of the harmful results caused by sewer and drain air was founded on quite unsatisfactory evidence. Actual infection of human beings by pathogenic micro-organisms carried from the sewage by sewer or drain air was now considered practically impossible, but the theory founded on very flimsy evidence that the inhalation of sewer or drain air lessened the resistance to infection remained.

In the discussion which followed there was a considerable amount of agreement with Dr. Wynne that too great importance had been attached to the harmful effects of sewer and drain air in the past, but the general opinion seemed to be that more research should be undertaken and that we must move cautiously till the subject is better understood. Dr. MEARNS FRASER mentioned that many practitioners attached importance to defective drainage as a cause of certain diseases. He asked why polluted soil did harm if drain air was harmless. Dr. A. WYNTER BLYTH gave the results of experiments conducted by him on the conditions under which micro-organisms can be discharged from sewage into the air. He had experimented with froths, bubbles, and splashes, and had found that a bursting bubble could only throw a micro-organism a distance of 4–6 inches. Whether a micro-organism so thrown could be carried along in a draught of air depended upon whether it was nude or covered with liquid. If nude it might be carried some distance in a light draught. Dr. Blyth advocated further research and that conclusions be not hastily accepted. Dr. SCURFIELD also favoured further research. It would be necessary to convince the Ministry of Health and its architectural department before by-laws could be altered. He had for 20 years advised his health committee that such diseases as typhoid fever and diphtheria could not be caught from drain or sewer air, but that health might be lowered by their inhalation so as to lessen resistance to infection. If drains were not watertight, leakage of sewage into or under the foundations of a house might go on for a considerable time without being spotted. Dr. A. MANKNELL (Bradford) mentioned the widespread belief aroused in the mind of the public by such books as Mr. Teale's, and pointed out that it was very necessary for the general practitioner to have a lead if there was to be a change of front. Dr. J. A. R. GLENNIE (Singapore) thought that the harmful effects put down to drain air might be due to rats. Many other speakers spoke as to the need for caution.

Prof. WYNNE, in replying, said he regarded sewage-polluted ground as a distinct danger. Traps were necessary to make drains rat-proof. Comparing drains with privies, the danger from a privy was not due to the smell, but to flies and the fouling of the streets at emptying times. Medical officers of health required guidance in this matter from scientific research workers like Dr. Blyth. He did not wish to be dogmatic, but we ought not to be satisfied with the vague idea that drain or sewer air lowers health and so causes disease.

Dr. E. B. HAZLETON (Sheffield) followed with a paper on the effect of long-continued inhalation of small doses of

Coal Gas in Causing Ill-health,

and especially in predisposing to tuberculosis. Since his attention had been drawn to the matter he had found that small leakages of coal gas were very common owing to defective construction of the taps. The taps which were at fault were those with stop-cocks at the bottom of the pipe. He had remedied the matter in his own house by adopting a catch which secured a gas-tight tap when the gas was turned off. He attributed the mischief to carbonic oxide, and had found that a leakage, quite insufficient to arouse attention by the characteristic smell, would at the end of the night give rise to a percentage of carbonic oxide in the bedroom, easily detectable by chemical analysis. He believed that the exposure to such air produced headache, anorexia, &c., and ultimately anæmia and he had had several striking cases in which tuberculosis was the ultimate result.

In the discussion which followed most of the speakers agreed that the matter was important and that there was much negligence on the part of householders in securing gas-tight fittings, and the hope was expressed that medical officers of health would follow up this question with a view to seeing if leaky gas taps are as common in their districts as in the experience of Dr. Hazleton.

EXHIBITION OF INSTRUMENTS, DRUGS, FOODS, AND APPLIANCES.

We have already commented on the excellence of the exhibition of surgical instruments, appliances, drugs, foods, and other objects which was held in the gymnasium of the Royal Naval Barracks at Portsmouth from Tuesday, July 24th, until Friday, July 27th. In the summary which follows notice is taken of exhibits presenting some new feature, the number of the stand being given for reference in square brackets.

SURGICAL INSTRUMENTS AND APPLIANCES.

The exhibit of surgical instruments, general and special, was particularly full and instructive. [52] John Bell and Croyden, Ltd., incorporating Arnold and Sons (50, Wigmore-street, London, W. 1): showed operating tables and hospital furniture, finished with a special non-chip enamel. Prominence was given to operation and accouchement outfits, to sterilised dressings, and to the "Marylebone" series of sutures and ligatures.—[63] Down Bros., Ltd. (21, St. Thomas's-street, London, S.E. 1): a large selection of new instruments, introduced and modified from existing patterns at the suggestion of operating surgeons, including Albee's instruments for bone grafting, Childe's hernia director and finger guard, Mott's dosimetric intratracheal anæsthesia apparatus, Carruther's saline infusion apparatus with unbreakable vacuum flask, and blood-urea instruments.—[36] The Genito-Urinary Manufacturing Company, Ltd. (66, Margaret-street, London, W. 1): the latest cystoscopes by Thomson Walker, Joly, Kidd, Andrews and Gordon, with urethroscopes by Joly, Powell, Kidd, Harrison and Young, also suprapubic drainage apparatus by Eynard, of Paris.—[65] The Holborn Surgical Instrument Co., Ltd. (26, Thavies Inn, London, E.C.): besides general surgical instruments and hospital furniture, a selection of glass and enamelled ware, a very complete assortment of midwifery bags, and an interesting collection of diagnostic apparatus, including the Holborn "pantoscope" for ear, nose, and throat examination, with additional attachments for trans-illumination of the frontal sinus and examination of the fundus oculi.—[17] Mayer and Phelps (59, New Cavendish-street, London, W. 1): a selection of instruments of original design for general and regional surgery, including the Revel-Moseley electric rotary pump for pressure and suction, available for removing blood and secretions from the operation area and for aspirating the chest and evacuating cysts. Among the intruments were Gillies's instruments for plastic surgery, Platt's chisels for operating in osteo-arthritis, and Walton's support for ptosis and after abdominal section.—[38] John Weiss and Son, Ltd. (287, Oxford-street, London, W. 1): a selection of instruments for use in general and ophthalmic surgery, calling particular attention to a new shadowless lamp for operation purposes.

Among the special instruments:—[29] "Acoustique" (95, Wigmore-street, London, W. 1): the "aid to hearing" in 25 distinct types as well as the acoustique stethoscope for doctors suffering from deafness, and an installation to enable deaf members of a congregation to hear the service.—[3] H. E. Curtis and Son, Ltd. (8, Old Cavendish-street, London, W. 1): various forms of abdominal belt and support, including an arrangement for colostomy, as well as "colonol," a liquid paraffin of Russian origin with a S.G. of 0·885 and viscosity of 295 to 300 secs. at 100° F.—[11] The Dowsing Radiant Heat Co., Ltd. (91, Baker-street, London, W. 1): the latest form of apparatus for radiant heat treatment by apparatus which is supplied on hire to medical men and institutions for any length of time.—[28] Horace V. Duncan (117, Commercial-road, Portsmouth): a number of original designs in artificial limbs, the "Victor" models being especially light in weight as well as silent and perfect in movement.—[19] Lindsay and Sons (7, Commercial-road, Portsmouth): abdominal belts, electric trusses, artificial limbs, appliances, and dressings as supplied to the Royal Portsmouth Hospital.—

] Watson and Sons (Electro-Medical) Ltd. (43,
arker-street, Kingsway, London, W.C. 2): the
Sunic " X ray outfit for private practitioners and
ottage hospitals, an oil immersed transformer type
mploying a 30 milliampère Coolidge tube in conjunc-
on with a combined couch and screening stand.—
] X Rays Limited (11, Torrington-place, London,
.C. 1): the latest design of combined couch and
reening stand, affording complete protection for
oolidge tube to comply with the standard set up by
e X Ray and Radium Protection Committee. The
nds of the box are covered with 9 mm. lead rubber,
e sides with 3 mm. of the same, and outside all is a
yer of 3 mm. of metallic lead.

Besides those firms mentioned as supplying dress-
gs:—[33] Antiphlogistine (Denver Chemical Mfg.
o., London, E. 3): the well-known product in the
ature of a hygroscopic antiseptic poultice, non-
ritating and non-toxic, keeping well in any climate
nd ready for immediate use.—[14] The Thermogene
ompany, Ltd. (Haywards Heath, Sussex): A
ientifically prepared cotton-wool impregnated with
imulating medicinal essences adapted for use as an
algesic and counter-irritant.

Drugs and Pharmaceutical Preparations.

The collection of drugs and pharmaceutical prepara-
ons was large and representative:—[2] Allen and
anburys, Ltd. (37, Lombard-street, London, E.C. 3):
erapeutic sera and vaccines issued by the Lister
stitute, as well as a number of organo-therapeutic
oducts, insulin, A.B. brand (manufactured jointly
ith British Drug Houses, Ltd.), a complete range of
oup-test protein solutions to be used in the diagnosis
hay fever, urticaria, &c., an efficient spirochæticide
the form of novarsan, and "butyn" a new local
æsthetic not coming within the scope of the
angerous Drugs Act. The same firm also showed
rgical instruments and appliances.—[69] Anglo-
rench Drug Company, Ltd. (238a, Gray's Inn-road,
ondon, W.C. 1): special pharmaceutical preparations
ch as diabetylin for the treatment of diabetes without
e withdrawal of carbohydrates, dimol, the intestinal
sinfectant introduced by Captain Ainslie Walker;
dyl, an arsenical compound for syphilis, approved by
e Ministry of Health, and neo-trepol, an anti-
philitic containing 96 per cent. of bismuth in isotonic
edium.—Modern Pharmacals, Ltd. (2, Calthorpe-
reet, London, W.C. 1): glucarsenol, a solution of
varsenobenzol in glucose with analgesics, in
npoules ready for use.—[45] Bayer Products, Ltd.
, Worple Way, Acton Vale, London, W.): a large
llection of synthetic drugs, among them adalin, a
pnotic and sedative, for use in neurasthenia, cardiac
uroses and pertussis, luminal and luminal-sodium,
datives in epilepsy, chorea and drug habit, nov-
pirin, protargol, sajodin, tannigen, veronal, and a
eparation designed to stimulate fibrosis in tuber-
lous conditions, known as guycose, being a 5 per cent.
lution of guaiacol-calcium-sulphonate in liquid
matose.—[67 and 68] John Bell and Croyden Ltd.:
isplay of "ramul" and "ramulettes," the ready-for-
e barium meal in X ray diagnosis, B and C brand
lysol, and "malobin," a children's tonic, being a
mbination of colloidal iron, red bone-marrow, and
alt extract.—[12] Boots Pure Drug Company, Ltd.
ottingham): a large assortment of synthetic and
edicinal chemicals, including acriflavine in crystal-
e form; stabilarsan, being a stable combination
salvarsan and glucose; alanin, uradal and others;
mpressed tablets of medicinal drugs and chemicals;
lution tablets in distinctive form for external
plication; flexible capsules and pastilles.—
7] C. J. Hewlett and Son, Ltd. (35, Charlotte-
eet, London, E.C. 2): a series of original
eparations, including deliciol, a soft paraffin for
estinal lubrication, iodermiol, a non-staining
eparation of iodine, physiologically standardised
ctures of ergot, digitalis, cannabis indica, scilla and
ophanthus, and a hypnotic, somnogen, an opium
eparation free from disagreeable after-effects.—
] Newton, Chambers and Co., Ltd. (331, Gray's Inn-road, London, W.C. 1): izal disinfectants, powders, soaps, along with mechanical sprayers.—[42] Oppenheimer Son and Co., Ltd. (179, Queen Victoria-street, London, E.C. 4): palatinoids and pulverettes, a series of colloids known as "oscols," standardised both microscopically and bacteriologically, roboleine, a reconstructive food for infants and invalids, and "pinheroin," a combination of terpene, heroin, and Canadian pine for use in laryngitis and chronic bronchitis.—[66] Parke, Davis and Co. (50, Beak-street, Regent-street, London, W. 1): pharmaceutical preparations including adrenalin gauze tape, medicinal peptone for use in cases of hypersensitiveness, mercurosal, a soluble organic mercury for injection, and protein extracts for diagnosis in more than 100 forms; also bacterial vaccines prepared at St. Mary's Hospital and antidiphtheritic serum of high concentration.

A number of special pharmaceutical preparations were shown. [81] The Anglo-American Oil Co., Ltd., Albert-street (Camden Town, London, N.W. 1): nujol, an intestinal lubricant of undeviating standard of viscosity; miscol, a solution of menthol, camphor, and eucalyptol in liquid paraffin for use in an atomiser in catarrhal affections and hay fever.—[56] Armour and Company, Ltd. (Queen's House, Kingsway, London, W.C. 2): digestive ferments, glandular preparations, and a glycerine extract of red bone marrow.—[41] G. W. Carnrick Co.'s standardised gland products (American Drug Supply Co., Ltd., 40, Lexington-street, London, W. 1): a series of organo-therapeutic products, selected from the glands of healthy food animals, such as hormotone for menstrual and menopausal disorders, trypsogen for diabetes mellitus, secretogen for gastro-intestinal disorders, and kinazyme in malnutrition.—[78] The Crookes Laboratories (22, Chenies-street, London, W.C. 1): along with other colloidal products, the recently introduced collosol-calcium for use in tuberculosis, malnutrition, and chronic sepsis, and collosol-kaolin in the treatment of intestinal toxæmia.—[20] The Danish Medicinal and Chemical Co., Ltd. (John Morgan Richards and Sons, Ltd., 46, Holborn Viaduct, London, E.C. 1): a concentrated pepsin-extract prepared and standardised by Dr. Ege. of Copenhagen University, citric acid tablets for achlorhydria, and various soft-mass pills containing an assimilable form of iron known as ferrolyt.—[13] J. C. Eno, Ltd. (Victoria Embankment, London, E.C. 4): a well-known effervescent saline laxative to assist in correcting some of the inevitable consequences of a civilised and artificial life.—[34] Genatosan, Ltd. (Loughborough): sanatogen, a true organic compound of casein and sodium glycerophosphate; genasprin, a pure form of acetyl-salicylic acid, cystopurin, and detoxicated vaccines including protein fractions of various bacteria.—[48] Jeyes' Sanitary Compounds Co., Ltd. (64, Cannon-street, London, E.C.): preparations of cyllin, characterised by high bactericidal power and slight toxicity, including inhalation, capsules, pastilles, dusting powder, and surgical soap; also Jeyes' lysol (jeysol), for use when a clear solution in water is required.—[44] The Chas. H. Phillips Chemical Co. (179, Acton Vale, London, W. 3): milk of magnesia, an antacid containing not less than 26 fluid grains of magnesium hydrate to the ounce, for use in milk modification and as a mild aperient; phospho-muriate of quinine compound, being an aromatic syrup for use as a general and nerve tonic.—[83] The Sandoz Chemical Co., Ltd. (Canal-road, Bradford): scillaren, being the cardiotonic glucoside of squill in tablets and ampoules; femergen, a new preparation of ergot free from unpleasant taste or smell; felamine, a combination of biliary acids of ox gall and hexamine for affections of the biliary system.—[82] Savory and Moore, Ltd. (143, New Bond-street, London, W. 1): the well-known food containing vitamins and approximating closely in composition to human milk; a new anæsthetic, ethanesal, containing ketones treated with CO_2 and ethylene dissolved in ether, and the fructole series of pharmaceutical preparations flavoured with a fruit base.—[23] The Semprolin Company, Limited (18, Leather-lane, London, E.C. 1): an emulsion containing

60 per cent. of paraffin oil of high viscosity; a special emulsion for infants with addition of carminatives known as carmex, and O.T.P., an oxygenated tooth-powder with a soluble base giving off nascent oxygen when moistened.

Toilet preparations were shown by several firms. [43] D. and W. Gibbs, Ltd. (Wapping, London, E. 1): superfatted soaps for tender and sensitive skins, various kinds of medicated soap, dentifrice, and dental cream.—[58] Kolynos Incorporated (Chenies-street, London, W.C. 1): an antiseptic dental cream capable of destroying pathogenic bacilli in the mouth as well as in vitro with no grit to abrade the enamel.—[55] The Pepsodent Company (42, Southwark Bridge-road, London, S.E. 1): a mildly acidic dentifrice containing acid calcium phosphate, stimulating the flow of saliva and removing mucin plaques, the polishing agent being tri-calcium phosphate.

(To be continued.)

Obituary.

FLORA MURRAY, C.B.E., M.D., B.S. DURH., D.P.H. CAMB.

Dr. Flora Murray, who died in London after a short and unexpected illness on July 28th, will be remembered for her large share in founding and maintaining the Women's Hospital Corps.

Flora Murray came from Dumfriesshire where her family have lived for over 500 years. Her father was Commander John Murray, R.N., of Murraythwaite, and her brother, the late Major Murray, was M.P. for Dumfries county. A student of the London School of Medicine for Women and of the College of Medicine, Newcastle-upon-Tyne, Dr. Murray graduated in medicine and surgery at Durham in 1903, proceeded to the M.D. degree in 1905, and a year later took the D.P.H. at Cambridge. Among the various appointments which she held after qualification were those of assistant physician to the Crichton Royal Institute, Dumfries, clinical assistant at the Belgrave Hospital for Children, and anæsthetist to the Chelsea Hospital for Women. She entered upon general practice in Kensington, throwing herself into her professional work with characteristic energy and devotion. In 1911 she founded a hospital for children in the Harrow-road, consisting of an out-patient department which extended rapidly, and of a ward of 12 beds. It was her hope later to build and to raise an endowment for an adequate hospital as a training centre for medical women in children's medicine. But the war intervened and expansion proved impracticable. Greatly to her regret, and that of the committee which she had gathered round her, the hospital was closed in 1921, after having done valuable work for ten years. The money collected for the hospital, mainly by her own efforts, amounted to £31,000, and has now in large part been vested in a trust under the name of "The Sea and Sun Club" for providing holidays and convalescent treatment for children of the neighbourhood.

A few days after war broke out in August, 1914, Dr. Murray offered her services first to the British War Office and then to the French Red Cross, and with other medical women she organised a women's unit for service in France. During the first six months of the war she helped to collect funds for and commanded two voluntary hospitals, each of 100 beds, first at the Hotel Claridge in Paris and then at Wimereux, near Boulogne. In 1915 Sir Alfred Keogh, Director-General of Medical Services, offered her the command of a larger military hospital in London and, from this time, the Women's Hospital Corps served under the British War Office. St. Giles's Workhouse, Bloomsbury, was placed at her disposal and, with the rank of lieut.-colonel, Dr. Murray became doctor in charge of the Military Hospital, Endell-street, with 600–700 beds, in addition to two auxiliary hospitals in the vicinity of London. The story of this admirable work is told with modesty and humour by Dr. Murray herself in "Women as Army Surgeons" (Hodder and Stoughton).

Her friend and colleague, Dr. Louisa Garrett Anderson, writes: "Dr. Flora Murray shared the pride and the humility, the traditions, and the love of country which are the inheritance of an old family. She was singularly fitted for the rôle of wise physician. Reticent and tactful, with wide sympathy and good judgment, grace of mind and body combined to give her a place in many hearts and her practice grew. She believed in youth and she gathered round her at Endell-street a company of young women and girls who justified her pride by their beauty and ability, and the fidelity with which they discharged the tasks she committed to their care. She had the power to lead women and to call out in others courage and self sacrifice equal to her own.

From a portrait by Mr. Francis Dodd.

DR. FLORA MURRAY.

"No account of Dr. Flora Murray would be complete without reference to the part she took in the struggle for the emancipation of women. Inevitably, she was a suffragist and, as inevitably, when she deemed militancy necessary, a militant suffragist. She was an admirable committee member, a good public speaker, and a keen politician. Her sympathies were strong and tender—for animals, for children, for working women, indeed for all women in their aspiration for freedom and opportunity; and the 32,000 men who passed through her hands during the war received their share of consideration and comradeship."

Dr. Flora Murray died in her fifty-fourth year. The funeral took place at Penn Church on August 1st, when a personal address was given by the Rev. William R. Rice, of the West London Mission, who during the war had acted as Wesleyan chaplain to the Endell-street Hospital. Sir William Leishman, D.G.M.S., represented the War Office, and the large gathering of friends included representatives from the oyal Free Hospital, the Elizabeth Garrett Anderson ospital, the London School of Medicine for Women, he London Association of Registered Medical omen, the Women's Freedom League, and the West slington Infant Welfare Centre. A number of he women who had worked under Dr. Murray as rderlies and nurses also were present.

WALTER WILLIAM CHAMBERLAIN, M.D., C.M. EDIN.,

MEDICAL OFFICER OF HEALTH, RAWDON URBAN DISTRICT, YORKS.

Dr. W. W. Chamberlain died suddenly at his resience in Rawdon on July 28th. On the previous night e went to bed in his usual health, but towards orning he had a heart seizure and died suddenly fterwards. Dr. Chamberlain was a graduate of the niversity of Edinburgh and in his younger days was noted athlete, being also at one time tennis champion f the South of Scotland. Graduating M.B. in 1887, e was subsequently house surgeon at the Royal nfirmary, Birmingham, and senior house surgeon at he Halifax Infirmary. Twenty-seven years ago he ettled at Rawdon, where his abilities secured for him n extensive practice, and where for many years he as medical officer of health for the township. His fforts were intimately associated with the interests f the Rawdon Convalescent Home and the Mitchell emorial Home. Some months ago overwork brought n a breakdown in health, from which he appeared to ake a quick recovery, but he died at the relatively arly age of 62. Dr. Chamberlain leaves a widow, two ons, and a daughter ; their loss will be widely shared y all who came into contact with his wisdom, indliness, and courtesy.

ANDREW STEWART, L.R.C.P. EDIN.,

CONSULTING SURGEON, BIRKENHEAD BOROUGH HOSPITAL.

BY the death of Dr. Andrew Stewart on July 30th, t the age of 69 years, Birkenhead has lost an able and opular medical practitioner. Dr. Stewart received is medical education at Liverpool University and at t. Bartholomew's Hospital, graduating in 1881. For en years or more before his death he had suffered om chronic myocarditis, but did not allow his isability to interfere with his work or pleasure. He ad long recognised that his death would be abrupt, nd spoke freely of it with great sang-froid ; the end ame very suddenly as he sat at his desk writing a tter ; he died as he lived, beloved and respected by ll who knew him. Dr. Stewart took a great interest n his professional work, was a diligent reader of the edical journals, a man of wide general culture, and ond of sport, particularly of boating and golf. He eaves a widow, son, and daughter to mourn their loss. is brother, Mr. Gershom Stewart, is a well-known ember of Parliament.

THE King has sanctioned the promotion from on. Associate to Knight of Grace of Surg. Lieut.-Colonel van Evans, T.D., in the Order of the Hospital of St. John f Jerusalem in England.

BLENDING BUTTER AND MARGARINE.—An important ase relating to the blending of butter and margarine was ecided at the Salford Police Court on August 1st. The efendants were the Ballochmyle Creamery Co., Ltd., of yrshire. The prosecutor proved that a sample of the lend bearing the label "Ayrshire margarine rolls blended ith pure butter," for which an inspector had paid 1*s.* a pound, ontained only 1 per cent. of butter, the prosecution contendg that notwithstanding the description, the article was othing but margarine and should have been sold as such. would appear that legally, while it is permissible to mix ith margarine butter not exceeding 10 per cent., the article ven in that case had to be sold as margarine. The general rice of margarine in Salford where the sample was bought as 6*d.* per pound, and on the specific date butter was *s.* 4*d.* per pound. The stipendiary magistrate said that per cent. of butter was not sufficient to make him think at it was fair to the purchaser, and imposed a fine of £20. eave to appeal was granted.

Correspondence.

"Audi alteram partem."

MEDICAL CHARITIES.

To the Editor of THE LANCET.

SIR,—The remarks of the treasurer of the British Medical Association at its annual meeting, reported in your last issue (p. 229), will, I hope, bring home to the medical profession the needs of the Royal Medical Benevolent Fund. Dr. G. E. Haslip's comments call for some reply, and especially for information as to the efforts that are being made by the committee of management to increase the income of the Fund. Dr. Haslip is (as he stated) a member of this committee and as such has a voice in the management. It is a matter of regret that owing to his many engagements and his recent illness he has not been able to attend as often as we could wish. The Medical Agency, of which Dr. Haslip is chairman, has contributed most handsomely to the Fund. These gifts have been acknowledged with gratitude not only by the committee of management and in the medical press, but by special letters from the treasurer.

The subscriptions collected through the medium of the Association amounted last year to £800. Moreover, through the kindness of the Editor of *The Lancet* and the Editor of the *British Medical Journal*, a summary of grants made is published monthly. Those who read their journals cannot but be informed of the existence and the needs of the Fund. The conference to which Dr. Haslip refers took place in 1922 at the request of the officials of the British Medical Association and was attended by representatives of Epsom College and of the Royal Medical Benevolent Fund. Dr. Haslip proposed that the two bodies should be amalgamated and that there should be a central bureau for the collection of subscriptions.

This proposal did not meet with the approval of either body as it involved the abandonment of organisations, metropolitan and provincial, for the collection of funds that had been built up by years of patient endeavour, without any sufficient assurance of their adequate replacement—and in the case of Epsom College there was the additional objection that such action would tend to restore to the College as a whole, which is a general public school of the ordinary type, a charitable aspect, that had been proven to be harmful to the College, as well as to the medical foundation incorporate in it, and which some 30 years ago was an important factor in inducing the council of Epsom College to obtain an amending Act of Parliament. It was felt also that the aims of Epsom College and the Royal Medical Benevolent Fund were essentially distinct, in that the former existed primarily for educational, the latter exclusively for charitable purposes. Seeing that so far as the Fund was concerned some 20,000 members of the profession do not belong to the British Medical Association it was considered wiser to remain free to appeal from one centre to the profession as a whole. This proposal would, moreover, entirely disorganise the present system of collecting subscriptions through local secretaries which adds a personal and sympathetic touch of no little value.

Dr. Haslip's effort in the cause of education and of charity was cordially appreciated by both bodies, and I hope will not be lost upon the profession. That the executive have not been idle in developing new ideas and methods during the last few years, the following brief account will indicate and will go some way, I hope, to remove the impression of apathy conveyed in Dr. Haslip's remarks. It is an error into which he could not have fallen had he been in closer touch with the management. During the last two years special appeals have been issued in the following towns : Bath, Birmingham, Bolton, Bristol, Bromley, Birkenhead, Bury, Cambridge, Cornwall, S. Wales and Mon., Surrey, Devonshire, Bootle, Manchester, Portsmouth, Buxton, Burnley, Weybridge, Watford, Sutton, Enfield, Blackburn, Altrincham, and similar appeals are being prepared for other towns this autumn.

Realising that printed matter is often thrown in the waste-paper basket unread, the various local secretaries have been asked to write out an appeal which has been reproduced, a stamped envelope is addressed to every non-subscriber, and sent to the local secretary who completes the letter by inserting the name. The reply is returned to the office or the local secretary as the latter desires. In some cases an addressed stamped envelope is enclosed for reply. Up to the time of writing over £400 in new subscriptions, largely in bankers' orders, have been received this year and replies are still coming in. Not only have these undertakings been initiated by the hon. secretary, Dr. Newton Pitt, but owing to the illness of the secretary the bulk of the work has fallen upon him. The festival dinner in 1913, at which £3197 was raised, at least informed the profession, the entire body being circularised of the existence and needs of the Fund. Taking the last two decennial periods, the income from investments and subscriptions amounted in 1902 to £3946, in 1912 to £6222, and in 1922 to £8080, the amounts distributed being respectively £3795, £5497, £8397. The number of grantees has increased from 140 in 1902 to 304 in 1922, and annuitants from 140 to 168.

The progress of the Guild, a branch of the Fund, is shown by the increase in income from £1725 in 1912 to £2536 in 1922. The progressive character and successful results of the Guild's work are well known. Notwithstanding all that is being done the income is far below what is needed, and it must, I fear, be recognised that the lack of support is due to the apathy of the profession and not the slackness of the committee of management or of its executive.

I am, Sir, yours faithfully,
CHARTERS J. SYMONDS,
Hon. Treasurer.

Royal Medical Benevolent Fund, 11, Chandos-street, W. 1, August 6th, 1923.

PS.—Since the above was written I have seen the letter which appeared in THE LANCET last week from Dr. Astley V. Clarke, explaining the method adopted by the practitioners on the panel in Leicester of subscribing to the Fund a farthing for each State-insured person. Last year this yielded £50. I hope, with Dr. Astley Clarke, that other insurance areas will follow the example of Leicester.

THE IMPERIAL CANCER RESEARCH CAMPAIGN AND THE CANCER PROBLEM.

To the Editor of THE LANCET.

SIR,—The labours of the Medical Research Council and of the administrators of the Imperial Cancer Research Fund have been distinctly disappointing, and I fear unless the promoters of the British Imperial Cancer Research Campaign exercise their functions as to the use of the moneys they secure very wisely and very well the knowledge gained may be equally disheartening and disappointing.

Before going to the public for the large sum of money they require to put cancer research on a hopeful basis, it would be well to ensure that the administrative side of the scheme should be worked out not by a committee of scientists and medical experts alone, but that men of proved administrative and business capacity should be added to it, and that when the scheme is decided upon its operation should be in the hands of such a hybrid committee, and that it should have such powers of control conferred upon it as would ensure efficient coördination and coöperation, the avoidance of overlapping, and the strictest economy in the carrying out of research in all its varied departments. This committee should have power to afford pecuniary aid and special facilities for using the resources of any or all institutions subsidised from their funds to individuals who in their opinion displayed unusual ability, originality, and initiative in research. The subsidy granted by the Treasury to the Imperial Cancer Research Fund is utterly inadequate, and during the debate on the Ministry of Health vote on June 28th, in response to my appeal, the Ministry admitted this, but unless the public shows decidedly that it is behind the Minister in this connexion I fear the Treasury will not find the necessary funds. In virtue of any subsidy granted by the House of Commons, the Minister of Health, officials of his department, and Members of the House should be represented on the committee.

In my view, however, the Minister can assist research in other ways than by subsidy, and that, too, to an extent and with an efficiency which he alone can bring to bear. I refer to the clinical side of research. He alone can procure and collate that mass of clinical information possessed by the medical practitioners throughout the country. Through his medical officers of health and their staffs, and the Registrar-General's department, every case of death from cancer notified might be investigated not by a lay official, but by the M.O.H. himself or his tuberculosis officer, and a questionnaire drawn up that might include all matters bearing upon possible cancer causation. Cancer areas, and there are such, might be mapped out. Cancer houses, and it is suspected there are such, might be located. Information might be gleaned from meteorological, geological, water, and food-supply experts, *et hoc genus omne.* No possible avenue of approach to cancer should be left unexplored, and this could best be done through the health departments of the various local authorities under the guidance of the Minister. We are so utterly ignorant of the causes and sources of cancer that we never know at what moment or from what direction illuminating knowledge may arrive.

I am, Sir, yours faithfully,
Blackpool, August 1st, 1923. LEONARD MOLLOY.

CANCER FACTS AND THEORIES.

To the Editor of THE LANCET.

SIR,—May I be allowed to add a few remarks, from a different point of view, to your admirable leading article with this title in your issue of July 28th.

The complete change in the whole aspect of cancer research as a result of the discovery of means by which primary cancer can be produced in laboratory animals hardly seems to be realised. Before this discovery was made an incalculable number of experiments were done with transmissible tumours derived from primary cancers. Upon this work a vast superstructure of theory was built and acres of paper wasted. In my own case I wasted several years working with these tumours produced by grafting, to find in the end that they had not the characteristics of primary cancer, that what would cure them with practical certainty had no effect on primary cancer, and that in fact the two were in no way comparable. There was at that time no practicable method of bringing primary cancer under experimental conditions either for observation or for the trial of treatments. Cases occurring in the human subject obviously cannot be brought under experimental conditions. Spontaneous cancer occurring in animals is equally unworkable. Only large numbers of superficial cancers observed at a sufficiently early stage and occurring more or less simultaneously would provide the necessary material. When these points are considered it will be realised that those engaged in cancer research laboured under a serious, if not hopeless handicap. This handicap is now removed as far as laboratory work is concerned. Primary cancer can be produced at will and observed under experimental conditions with the full advantage of controls and every other necessary check. All excuse for premature experiments with probable or improbable cures upon the human subject is removed.

In these circumstances I think it is desirable that full credit should be given to those who made this covery, Yamagiwa and Schikawa of the University Tokyo. An account of the experiments by which y produced cancer in animals by the application coal tar, externally and by injection, is available the *Journal of Cancer Research*, January, 1918. ch and Driefuss were conducting researches on the ect of coal tar in the production of cancer in 1912 resumed the work in 1920. In mice they produced cer with the whole tar and also with some of its ferent elements. They claim to have isolated the cer-producing constituent of the tar.[1] They had n, however, forestalled by the Japanese. If it true as you say in your leading article that probably hin the next few years we may see "results in the gnosis and treatment of malignant disease which ld not have been foreshadowed a very few years " and these results are achieved along the lines suggest, then I think it should be clearly understood that the discovery that made this advance sible was the experimental production of primary cer in laboratory animals.

I am, Sir, yours faithfully,

CHARLES WALKER.

niversity of Liverpool, July 30th, 1923.

OPHTHALMOLOGICAL TRAINING FOR MEDICAL STUDENTS.

To the Editor of THE LANCET.

IR.—A not inappropriate comment on Mr. Percy mming's letter in THE LANCET of last week, relative the use of the ophthalmoscope in general practice, y be found in a sentence written more than 50 years by the distinguished physician who is now the gius Professor of Physic in the University of nbridge. The sentence runs: "Every medical ool is now . . . . bound to teach its students the of the ophthalmoscope as carefully as the use of the hoscope is taught." The task which Sir Clifford outt accepted in 1871 Mr. Flemming in 1923 proes to abandon. This is the more astonishing seeing the difficulties of the earlier date have been largely uced by the introduction of the electric ophthalmoe, and yet I should be inclined to accept Mr. nming's conclusion if, as he appears to decide, ruction and practice in the use of the ophthalmoe must be limited to the brief period spent by the lent in the ophthalmic department. If, however, exhortation conveyed in Sir Clifford Allbutt's parison is accepted, no such limitation can be wed. For the use of the stethoscope is taught by pelling the student to practise the instrument on y patient, as in this way alone can he acquire the itory standard which enables him to recognise both limits of the normal and departures, slight or gross, the accepted level. And when in the medical ds and out-patient service the ophthalmoscope is ht and practised as the stethoscope is taught practised—and the enterprise is easily accomed—the student will become as expert with the instrument as with the other. With neither can e expected to appreciate, without a long experi, the finer shades of change produced by disease. in each instance he is provided with an opportunity the self-education which is the avenue to expert ment, and if the medical curriculum affords and rces this opportunity it has largely fulfilled its . To abandon the ophthalmoscope as beyond scope of general practice because all its values not be obtained in some few weeks passed in an halmic department would be as reasonable as to don the stethoscope because, even at the end of curriculum, not all its possibilities have been ired. Let the fashion of instruction in the one be equally applied to the other, and there can be oubt that with each there will be one and the same dard of success.

I am, Sir, yours faithfully,

ndon, W., August 6th, 1923. C. O. HAWTHORNE.

PHYSICAL AND RECREATIONAL TRAINING.

To the Editor of THE LANCET.

SIR,—As one of those who were privileged to be present at the demonstration of physical and recreational training held before the B.M.A. at their recent meeting in Portsmouth, an account of which was given in your issue of last week, may I express the hope that the benefit of this kind of training shall not remain confined to the Navy. I suppose we most of us feel that our board school education fails to develop certain sentiments and elements of strong character which the Naval School of Physical and Recreational Training has managed to include.

It is to be hoped, therefore, that the principles involved will not be lost to sight by the educational authorities of this country, but that steps will be taken with the object of founding a national school of physical and recreational training, so that there may be gradually accumulated an ample supply of skilled instructors. For while there is an unquestionable need for this particular kind of training among the masses, it can be satisfactorily carried out only by teachers who have themselves undergone a thorough course of practical instruction in the principles upon which the system is based.

I am, Sir, yours faithfully,

Southsea, August 2nd, 1923. HAROLD BURROWS.

AN EPIDEMIC OF ERYTHEMA NODOSUM.

To the Editor of THE LANCET.

SIR,—With reference to the annotation on this subject in THE LANCET of July 28th (p. 180), giving details of Prof. E. Ledoux's paper in the *Revue de Médecine*, may I call the attention of your readers to an instructive monograph on erythema nodosum by Dr. A. A. Lendon of Adelaide? It is a little unfortunate, perhaps, that the author gave it the title of "Nodal Fever" (1905). For that reason it may have been overlooked by those interested in the subject. Dr. Lendon came to the conclusion as a result of special observation that the condition was *sui generis*, and, from what I have observed, I am inclined to agree with Dr. Lendon.

I am, Sir, yours faithfully,

London, W., August 3rd, 1923. GEORGE PERNET.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. M. P. Jones is placed on the Retd. List with the rank of Surg.-Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

The Royal Naval Volunteer Reserve Officers' Decoration has been conferred upon Surg.-Capt. A. R. Brailey.

The undermentioned appointments are made at the War Office: Lt.-Gen. Sir W. B. Leishman, F.R.S. (late R.A.M.C.), to be Director-General vice Lt.-Gen. Sir T. H. J. C. Goodwin (late R.A.M.C.), who is placed on retired pay.

ROYAL ARMY MEDICAL CORPS.

Maj. W. Davis to be Lt.-Col., vice Lt.-Col. G. H. Goddard (ret. pay).

Temp. Capt. T. Brodie relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. T. S. Goodwin (late R.A.M.C.) to be Capt.

D. R. Lewis and T. D. Overend to be Lts.

General Hospitals: The undermentioned relinquish their commns. and retain their rank except where otherwise stated: Capts. G. M. Benton (granted the rank of Maj.), J. P. Buckley, E. Moir (granted the rank of Maj.), T. P. McMurray, and H. H. Rayner.

ROYAL AIR FORCE.

Squadron Leader F. C. Jobson is transferred to Reserve, Class D.2.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Adjournment of Parliament.

Parliament adjourned on Thursday, August 2nd, for the summer recess. It will reassemble on Nov. 13th.

HOUSE OF LORDS.

Wednesday, August 1st.

Dentists Bill.

The Dentists Bill was read a third time and passed.

HOUSE OF COMMONS.

Wednesday, August 1st.

Public Health.

On the motion for the third reading of the Consolidated Fund Bill,

Mr. Rhys Davies asked the Minister of Health whether he had any further information relative to the shortage of hospital accommodation in this country. While there were 30,000 empty beds in the Poor-law hospitals there were not many short of 100,000 people waiting for admission to the ordinary hospitals. In one London hospital there were 300 persons on the waiting list for 15 beds. He did not blame the Minister for this state of things, but he thought it was his duty to carry out the recommendations of the 1921 committee of inquiry. He wished to protest against the action of certain employers in Gloucester who had given notice of dismissal to their employees who refused to be vaccinated. He hoped that the Minister would come to the rescue of these people who objected to vaccination, because some people thought that the whole thing which had been boosted in the press as a small-pox scare was merely a "stunt" on behalf of some newspapers. The Minister of Health had received a deputation that week from the Lancashire Insurance Committee supported by Members of the House relative to an arrangement which it was suggested should be made between Mr. Spahlinger and the Ministry of Health. He was sorry to learn that the result of the negotiations so far was not very encouraging. He thought that the Minister would agree that the treatment of consumption had reached a deadlock. Sanatorium treatment after all was merely a treatment to ward off the disease. The deputation asked the Minister to support Mr. Spahlinger by way of a grant or subsidy and not only by way of purchasing the serum. He believed that the Minister had gone so far as to say that he was prepared to set aside a separate institution with 40 or 50 patients upon whom experiments could be made with the new treatment, but Mr. Spahlinger was not able financially to accept an agreement of this kind. He appealed to the Minister to come to Mr. Spahlinger's aid.

Mr. March said that in his district there had been a big increase in tuberculosis since the war and they had had the sanction of the Ministry of Health to have two doctors to attend to the patients. But during the summer holidays they had only one doctor instead of two. The consequence was that the patients had to be neglected for two months. They were also informed that extra nourishment was not to be granted to these patients. They were also informed that they were not to spend so much money in milk at their maternity and child welfare centres. He hoped that the Minister would help those local authorities who desired to do all they could to keep the people healthy.

Lieut.-Colonel Hodge said that the Spahlinger cure had proved efficacious in 80 per cent. of the cases treated. Mr. Spahlinger, however, was in difficulties to the extent of about £100,000. But only £24,000 of that amount was pressing. But for the sum of £100,000 they could obtain his laboratory, the whole of his estate, his father's estate, which was at present in the hands of the bank on mortgage. Mr. Spahlinger was willing to hand them over on trust for ten years. He only asked further for a sum of money to allow him to continue his research. He had gone the length of saying that they might appoint a committee to record how the money was spent. For the sum of £100,000 and a subsidy of £10,000 a year for three years Mr. Spahlinger was prepared to give the Minister of Health 50 per cent. of his sera and his vaccine.

Lord Eustace Percy, Parliamentary Secretary to the Ministry of Health, said that on Jan. 1st the number of empty beds in the Poor-law infirmaries was just over 6000, or about 18 per cent. Considerable steps were being taken all over the country for the better organisation and utilisation of the space in the Poor-law infirmaries. As regarded the point about employers and vaccination in Gloucester, if he were in that town he should certainly claim the right to protect his household from risk by refusing to take int his private employment any person who was not vaccinated and he should regard it as a gross form of tyranny if th State told him not to do so. There was a grant at any rat in certain cases and areas for extra nourishment for peopl suffering from tuberculosis. In regard to Mr. Spahlinge the Ministry of Health sent out a specially qualified office to Switzerland in 1922, and on receipt of that officer's repor the Ministry, in August last year, made a proposal to M Spahlinger which he was unable to accept. Arrangement made between the Red Cross Society and Mr. Spahlinge also fell through. This year there had been a renewal c the negotiations and the Minister had seen Mr. Spahlinge The position was this. The Government were intereste in the Spahlinger treatment and they were satisfied tha there was a prima facie case for such further scientifi inquiry as would enable medical authorities and the worl in general to form a definite and final opinion as to it efficiency. But if there was to be any question of th expenditure of public funds Parliamentary sanction woul be necessary, and the Government would not be justified i asking for such sanction except on the basis of adequat information and reasonable security. In the opinion of th Minister of Health these conditions could best be satisfie by asking Mr. Spahlinger to take an early opportunity making a full statement of his process and results to a bod competent to pass expert opinion upon it. His right hon friend understood that such an opportunity was bein afforded in this country, and when Mr. Spahlinger had take advantage of it it should be possible to arrive at a decisio as to what action, if any, could appropriately be taken b the Government. Meanwhile the Minister hoped that th appeal which was now being made for funds from privat sources might be successful in meeting the immediat difficulties of Mr. Spahlinger's position.

The Bill was read a third time.

Cost of Inmates of Poor-law Institutions.

Mr. Cecil Wilson asked the Minister of Health th annual cost per head for England and Wales of the inmates Poor-law institutions, distinguishing between children homes, infirmary, and other inmates respectively.—M Neville Chamberlain replied : The annual cost per hea for the year ending March 31st, 1921, for England and Wal of the inmates of the several classes of Poor-law institution was as follows :—

	£	s.	d
Homes for children	73	18	7
Poor-law infirmaries and other Poor-law institutions for persons suffering from infirmity of body or mind	148	12	1
General Poor-law institutions	78	14	7
All classes of Poor-law institutions	88	5	3

Venereal Disease Disinfectants.

Mr. Peto asked the Minister of Health whether he ha consulted the Law Officers of the Crown as to the effect the Venereal Disease Act, 1917, in connexion with the repo of the committee of inquiry on venereal disease under th chairmanship of Lord Trevethin ; and, if so, whether could give the House their opinion as to the position chemists under the Act and the necessity for legislation, effect was to be given to the recommendations in Clause 1 of the committee's report.—Mr. Neville Chamberlai replied : I have consulted the Law Officers of the Crown to the effect of Subsection 2 of Section 2 of the Venere Disease Act, 1917, and I am advised by them that there nothing in that subsection to prevent a chemist from sellin disinfectants for the prevention of venereal disease whe no written or printed instructions are affixed to or delivere with the disinfectant, or from giving verbal recommenda tions of medicinal preparations intended to be used or applie for the purpose. In the light of this opinion it woul appear that legislation would be necessary in order permit written or printed instructions to be supplied wit the disinfectant or to restrict the existing powers of chemis by confining them to the sale of articles, the composition which had been approved by a competent authority.

Deaths from Measles.

Sir Robert Newman asked the Minister of Health if th deaths resulting from measles had increased since th compulsory notification of that complaint had been abolishe —Mr. Neville Chamberlain replied : There has been n such increase. The average number of deaths from measl during the past three years has been 5042 per annum compared with 7318 per annum for the four years, 1916 t 1919, during which the notification of measles was compulso throughout the country.

Advertisements on Medical Certificates.

Mr. Raine asked the Minister of Health if he was awa that there were large stocks of certificates with advertis ments on the reverse side in the hands of some of the industri nsurance companies ; and would he, in view of the strong xception taken by the medical profession to such certificates eing issued, cause these stocks to be replaced by the new ertificates which were now being printed.—Mr. NEVILLE HAMBERLAIN replied : The hon. Member has been misnformed. Certificate books are issued to insurance committees and not to approved societies. A new supply ithout advertisements will be available shortly, but I annot undertake to withdraw the books already issued to ractitioners.

Vaccination and Small-pox.

Mr. LEACH asked the Minister of Health whether he had ny official information that it was the practice in the Jnited States to carry out vaccination by means of a single nsertion only, and had it been found that this method was s protective against small-pox as the official four marks nethod adopted in this country.—Mr. NEVILLE CHAMBERLAIN eplied : I have no official information as to the method of accination in the United States of America. The Royal ommission on Vaccination concluded that vaccination in our places giving a total vaccination area of half of a quare inch is more effectual and gives better protection gainst small-pox than is afforded by one place or a less accinated area.

Mr. PALING asked the Minister of Health whether, on ept. 1st, the form of statutory declaration of objection to accination contained in the notice of the requirements of he Vaccination Acts given by the registrar when a birth as registered was to be dropped ; and whether, under new order to be issued on the above date, every parent ishing to get exemption for his child was to be compelled o go to the vaccination officer for the form.—Mr. NEVILLE HAMBERLAIN replied : The answer to the first part of the uestion is in the affirmative and to the second in the negative. he effect of the new order, which has already been issued, that from and after Sept. 1st any parent wishing to make statutory declaration of conscientious objection to vaccinaion may obtain a form of declaration from the vaccination fficer, or may make a declaration in the form prescribed y the Vaccination Act, 1907, or in a form to the like effect.

Mr. BROAD asked the Minister of Health how many eaths from small-pox were registered from 1906 to 1920 ; ow many chicken-pox deaths were registered in the same eriod ; and whether in view of the statement of the egistrar-General in his report for the year 1889 that it was robable that most of the deaths registered as due to chickenox were in reality cases of modified small-pox, he would ave the vaccinal condition of the deaths from chicken-pox tated on the death certificate, and also have such cases ncluded in those of small-pox.—Mr. NEVILLE CHAMBERLAIN eplied : The particulars asked for are as follows :—

England and Wales.

ear.	Deaths from—		Year.	Deaths from—	
	Small-pox.	Chicken-pox.		Small-pox.	Chicken-pox.
906	21	106	1914	4	122
7	10	120	15	13	92
8	12	93	16	18	65
9	21	94	17	3	69
10	19	97	18	2	54
11	23	80	19	28	55
12	9	76	20	30	71
13	10	83			

The suggestions in the last part of the question will eceive consideration.

Asylum Superintendent's Appointment.

Major MCKENZIE WOOD asked the Minister of Health hether he had received any protest from the medical rofession in Lancashire with regard to the appointment of he superintendent of Prestwich Asylum, Manchester ; and hat action he proposed to take in the matter.—Mr. EVILLE CHAMBERLAIN replied : The Board of Control have eceived no official information of the appointment of a nedical superintendent at Prestwich Mental Hospital, ut they understand that an appointment, to which strong xception is taken, was made last week by the Lancashire sylums Board. The appointment rests with that body lone, but the Board of Control in January last suggested hat it would be of advantage if they were consulted in egard to it. I do not know why this advice has not been cted upon, but the Board of Control propose to make some nquiry about the appointment.

Maternity and Child Welfare Centres.

Mr. TURNER asked the Minister of Health if his department were taking any special steps to develop maternity nd child welfare clinics so as to cope with and help to reduce he death roll of ten per day occurring amongst women uring pregnancy and childbirth.—Mr. NEVILLE CHAMBERLAIN replied : I am well aware of the continued high rate of maternal mortality associated with childbirth, and under the Maternity and Child Welfare Act I am endeavouring to encourage the establishment and development of maternity and midwifery services (including antenatal centres, maternity hospitals, and the provision of midwives). I hope that by such means the present death-rate will be progressively and substantially reduced.

Deaths of Women in Childbirth.

Mr. RHYS DAVIES asked the Minister of Health the percentage of deaths of women on confinement in this country for each of the last ten years and for periods of ten years prior ; and how those figures compared with records in other countries.—Mr. NEVILLE CHAMBERLAIN replied : Figures for England and Wales in regard to deaths of women assigned to pregnancy or childbirth for the last ten years and for decennia from 1861 to 1910 are given in the following table together with such figures as are available in regard to other countries :—

Deaths of Women Assigned to Pregnancy or Childbirth.

A = Deaths per million living. B = Deaths per 1000 births.

—	England and Wales.*		Holland.†		Italy.		Japan.		Switzerland.		Sweden.	
	A	B	A	B	A	B	A	B	A	B	A	B
1861–70	341	4·70	—	—	—	—	—	—	—	—	—	—
1871–80	350	4·72	—	—	—	—	—	—	—	—	—	—
1881–90	318	4·73	—	—	—	—	—	—	—	—	—	—
1891–1900	301	5·09	—	—	—	—	—	—	—	—	—	—
1901–10	206	4·01	—	—	—	—	—	—	—	—	—	—
1913	185	3·96	—	—	—	—	—	—	—	—	53	2·28
1914	192	4·17	—	—	75	2·41	—	—	—	—	58	2·60
1915	176	4·18	—	—	—	—	120	—	—	—	63	2·90
1916	166	4·12	134	2·58	59	2·45	—	—	64	3·37	56	2·66
1917	132	3·89	131	2·53	56	2·86	120	3·59	44	2·42	51	2·46
1918	127	3·79	147	3·00	—	—	—	—	49	2·62	—	—
1919	154	4·37	161	3·35	—	—	—	—	60	3·19	—	—
1920	210	4·33	—	—	—	—	—	—	62	2·93	—	—
1921	168	3·91	—	—	—	—	—	—	—	—	—	—
1922	149	3·81	—	—	—	—	—	—	—	—	—	—

* Prior to 1911 puerperal nephritis and albuminuria were not classed to pregnancy and childbirth and consequently the rates shown from 1913 onwards are from ·22 to ·25 in excess of what they would have been under the old classification.

† The number of deaths per million living in Holland for 1911–15 (inclusive) was 126. The number of deaths per million living in Denmark in 1920 was 60 and the number per 1000 births was 2·35.

Tuberculosis in the Navy.

Lieut.-Colonel MOORE-BRABAZON asked the First Lord of the Admiralty the number of men, categoried in branches, who had been discharged from the Navy with tuberculosis in the last three years.—Major BOYD CARPENTER replied : No statistics have been prepared for 1920, and the figures for 1922 are not yet available. The following table gives the figures for 1921 :—

Classes.	No. of cases.	Ratio per 1000 of average number borne.
Commissioned officers	10	1·77
Subordinate officers	—	—
Warrant officers	2	0·69
Seamen	103	2·46
Boys	14	1·69
Engine-room ratings	75	2·50
Marines	24	3·20
Stewards and cooks	5	1·33
Sick-berth staff	6	4·27
Regulating branch	—	—
Writers	8	8·77
Victualling ratings	3	4·49
Ships cooks	3	1·71
Armourers and blacksmiths	—	—
Other artisans	3	0·83
Kroomen, seedies, and lascars	—	—
Telegraphists	8	2·76
Miscellaneous ratings	—	—

Child's Death in Hospital.

Mr. GILBERT asked the Minister of Health whether his attention had been called to an inquest held on a child in one of the hospitals of the Metropolitan Asylums Board, at which charges were made by nurses against the doctor who attended the child ; whether he proposed to hold any inquiry into the case ; and could he make any statement on the subject.—Mr. NEVILLE CHAMBERLAIN replied : I have received a report upon this case from the Metropolitan Asylums Board, of which I will send the hon. Member a copy. It will be seen from the report that a full inquiry was held by the coroner, that the jury found that the death of the child was due to natural causes, and that the statements made by the nurses contained serious discrepancies. The nurses have been reprimanded for their failure to make an immediate report of the occurrences which they allege took place. Under all the circumstances I do not think that further inquiry on my part would serve any useful purpose.

Replying to a further question, Mr. Chamberlain said that he believed that the doctor had since resigned, but he could not state the reason for the resignation.

Thursday, August 2nd.

Highbury Pension Hospital Fire.

Mr. Macpherson asked the Minister of Pensions whether the committee which was appointed by him to enquire into the cause of the fire at Highbury Pensions Hospital and to make recommendations for the prevention of fire in the future at Ministry hospitals had yet reported, and if so, whether the report would be published.—Major Tryon replied: I have just received the report of this committee and I am arranging for it to be published.

Grant for Combating Venereal Disease.

Mr. Albert Bennett asked the Prime Minister whether the Government would consider the allocation of the £12,000 annual grant for combating venereal disease between the Society for the Prevention of Venereal Disease and the National Council for Combating Venereal Disease; whether he was aware that the latter organisation was the only one in receipt of any State assistance; and why, seeing the Trevethin report had been unconditionally accepted by both, there was any differentiation made in respect to the Government assistance given.—Mr. Neville Chamberlain replied: As regards the first part of the question, the maximum grant which will be paid from the Ministry direct to voluntary organisations in aid of their work in combating these diseases is £7500. The answer to the second part is in the affirmative. As regards the third part, the question of Government assistance to the work of voluntary organisations will come up for review in connexion with the recommendations in the Trevethin Report which is now under consideration.

Oxford and Cambridge Grants.

Mr. Charles Buxton asked the Secretary to the Treasury whether he would take steps to obtain and publish annual returns from Oxford and Cambridge Universities in the same form as those now published in respect of other universities in Great Britain under the auspices of the University Grants Committee.—Sir W. Joynson-Hicks replied: I have requested the University Grants Committee to take such steps as appear practicable to obtain from the university authorities at Oxford and Cambridge returns which will be as nearly comparable as circumstances permit with those annually supplied to the Committee by other grant-aided university institutions and published in the Committee's Blue Book. The hon. Member will, however, appreciate that the conditions at Oxford and Cambridge differ in certain material respects from those which prevail at the other universities, and that as the records and accounts at the two ancient universities have not hitherto been kept with a view to returns on the lines which are required by the University Grants Committee, a little time may elapse before properly comparable figures for Oxford and Cambridge can be provided.

Medical News.

University of Edinburgh.—At the graduation Ceremonial on July 20th the following degrees were conferred:—

Doctor of Medicine.

Alfred F. Adamson, Robert A. Chambers (in absentia), Jacob D. M. Claassens, *James H. Clarke, William H. Dickinson, James F. Duncan, *Basil A. G. A. Edelston, †Joseph H. Fairweather, Thomas J. Howell, †Hugh A. Macmillan, ‡Robert Mailer (in absentia), †Gerald I. Moriarty, *James P. Watt, and ‡Harold W. Wilson.

* Commended for thesis. † Highly commended for thesis.
‡ Awarded gold medal for thesis.

Bachelor of Medicine and Bachelor of Surgery.

James N. Adam, Stuart F. Allison, David G. Anderson, David T. Anderson, Edward W. Anderson, Hope P. Anderson, David Band, John S. Banks, Charles Bateman, Elizabeth A. Baxendine, Ralph S. Begbie, Malcolm J. Bett, Alexander Beveridge, Helen Blacklay, Anna L. Blair, Charles E. M. Blumer, Harriette G. Bogle, Jane P. S. Bow, George P. F. Bowers, Margaret G. Bowie, Edwin F. Boyd, William Boyd, Robert D. Bradshaw, Donald Brims, Norman M'Dowell Brown, William N. Brown, William J. Burns, Thomas D. Burt, Andrew J. M. Butter, Eva T. Cairns, Flora H. M. Price, Jean R. Purves, Adam L. K. Rankin, John Reid, Robert J. Reid, James S. Riddle, Frank L. Rifkill, Richard P. A. Rigg, Hilda C. Roberts, Ian M. Robertson, Gilbert M. Ross, Alexander A. M. Sandison, Pincus Schneiderman, William C. S. B. Sewrey, Donald A. M. Shearer, Bertram Siddons, William A. Simpson, James Sinclair, Cecil Siung (in absentia), James M'Ildowie Smellie, Arthur B. Smith, Arthur F. Smith, Dorothy F. Smith, Jean L. Smith, Sydney M'Kendrick Smith, George Somerville, Robert C. Speirs, Alice Steven, Donald B. Strachan, *John Sturrock, Theodotus J. Sumner, Hector W. Sutherland, Charles J. Swanson, Richard E. M. Taunton, Leslie M. Thompson, Vera Thompson, Elsie Thomson, Frank B. Thomson, George H. Thomson, Kenmure J. Thomson, Mahmoud S. Toukhy, John Trotter, Thomas Tully, Anne M. Turnbull, Duncan A. Urquhart, Edward R. C. Walker, Forbes M'Donald Walker, Edgar P. Waters, William N. B. Watson, George M. Westwood, *Adam Cairns White, Illtyd G. Williams, John H. Williams, Norman B. Williamson, Charles R. Wilson, Jeanie Wilson, Mary Wilson, *William Muirhead Wilson, John F. S. Wiseman, Gerald K. Wood, Eric D. M. Wright, David H. D. Young, James B. Young, and James N. Young.

† First-class honours. * Second-class honours.

Diploma in Public Health.

Esther J. Campbell, Mary C. Campbell, Grace Cumming, Gladys H. Dodds, Thomas Ferguson, Elspeth L. Gilmour, Elizabeth R. Kemp, Catherine A. J. Mitchell, Dorothea M. Norwell, Annie C. Roberts, Jessie W. Strang, Isabella Taylor, Annie E. Webster, and Doris S. Williams.

The following awards were also made: Thesis Gold Medallists: Robert Mailer and Harold W. Wilson. Cameron Prize in Practical Therapeutics: John J. R. Macleod. Gunning Victoria Jubilee Prize in Materia Medica: John H. Crawford. Gunning Victoria Jubilee Prize in Forensic Medicine: Douglas J. A. Kerr. Gunning Victoria Jubilee Prize in Obstetrics: Douglas A. Miller. Ettles Scholarship and Leslie Gold Medal: Robert Carmichael. Allan Fellowship in Clinical Medicine and Clinical Surgery: John Gray. Murchison Memorial Scholarship in Clinical Medicine: John Gray. M'Cosh Graduate's and Medical Bursaries: William N. B. Watson. Beaney Prize in Anatomy and Surgery: Caroline A. Elliott. Mouat Scholarship in the Practice of Physic: James L. N. Dinwiddie. Conan Doyle Prize: Gabriel G. King. Annandale Gold Medal in Clinical Surgery: John M. Cowan. Buchanan Scholarship in Gynæcology: Ian M. Robertson. James Scott Scholarship in Midwifery: Frank B. Thomson. Scottish Association for Medical Education of Women Prize: Caroline A. Elliott. Dorothy Gilfillan Memorial Prize: Harriette G. Bogle. Wellcome Medals in the History of Medicine: Gold Medal, James Aitken; Silver Medal, Donald G. S. M'Lachlan. Wightman Prize in Clinical Medicine: William J. A. Coldstream. Cunningham Memorial Medal and Prize in Anatomy: George Brown. Whiteside Bruce Bursary: Ian G. W. Hill.

Prudential Assurance Company and Medical Research.—The board of management of the Hospital for Sick Children, Great Ormond-street, London, whose Chairman is the Earl of Wemyss, have decided to establish a Research Department in which highly trained experts may study the life histories, conditions of growth, &c., of living agents of children's diseases. Examination revealed the fact that some £2000 would be required each year for the working of the Research Department; the board appealed for financial help to the Directors of the Prudential Assurance Company, on the ground that the proposed research work would promote longevity and the development of a healthier and more virile race. As a result, the Directors of the "Prudential" consented to provide the money required for the first year.

London Hospital.—The old students' dinner of e London Hospital will be held at the Trocadero Restaurant Wednesday, Oct. 3rd, at 7.30 for 8 p.m.

The Schorstein Memorial Lecture in Clinical Medicine ill be delivered by Dr. Gordon Holmes in the Medical ollege of the London Hospital during the winter term.

London Hospital Medical College.—A lecture the Value of Accurate Small-pox Diagnosis will be livered in the Anatomical Theatre of the College by Dr. W. cConnel Wanklyn, principal assistant medical officer of alth, London County Council, on August 15th.

St. Thomas's Hospital Medical School.—ntrance Scholarships for the year 1923 have been awarded under: Entrance Arts Scholarship (value £50): Mr. . H. Le Good (Alleyn's School). Entrance Science Scholar-ips: (1) Mr. H. C. Trowell (Reigate Grammar School) alue £150; (2) Mr. I. J. Jones (St. Thomas's Medical chool) value £60. William Tite Scholarship (value £25): r. J. B. George.

Fellowship of Medicine and Post-Graduate edical Association.—A special course of post-graduate ctures in infants' diseases, for medical officers of welfare ntres and others, will be given at the Infants' Hospital, ncent-square, Westminster, London, S.W., from Sept. 3rd 21st. The fee for the course is £5 5s., and the names of ose wishing to attend should be sent at once to the Secre-ry of the Fellowship, 1, Wimpole-street, W. 1. The dates the lectures will be announced in our Medical Diary.

Walsall M.O.H.: A Compromise Reached.—me time ago the Walsall Town Council offered a salary of 00 per annum as the salary for the borough medical officer. he British Medical Association stipulated that the amount ould be £1100, and a dispute thereupon arose, with the sult that there was not a single application for the pointment. On August 4th a compromise was reached, d Dr. J. A. Clark, borough tuberculosis officer, was pointed at a salary of £900.

Dr. Michael J. Nolan, resident medical superin-ndent, Down District Asylum, Downpatrick, Co. Down, s been elected President of the Medico-Psychological ciety of Great Britain and Ireland. Dr. Nolan is probably e only man to hold office under both the Irish Free State d the Government of Northern Ireland, being consulting sitor in lunacy to the Lord Chief Justice of either country.

Royal Northern Hospital.—The hospital board management announce that the £20,000 which was needed July 31st to prevent the closing of wards in the four stitutions under their control has not been obtained. nsequently they have had no alternative but to close 70 ds. Although the appeal was widespread, only £1500 have en received towards this fund. This closing of 70 beds eans that over a period of a year another thousand cases ill have to be refused admission for treatment.

Donations and Bequests.—The late Mr. Hugh llerton, of Brackenhoe, Sale, Cheshire, has left £5000 to e Christie Hospital Cancer Pavilion (if not already given), r assisting in carrying on scientific investigation in relation cancer; £500 each to the Whitehaven and West Cumber-nd Infirmary and the Manchester Royal Infirmary; and 00 each to the National Lifeboat Institution, the Royal ye Hospital, the Northern Hospital for Women and ildren, Henshaw's Blind Asylum, the Deaf and Dumb stitution, the Royal Schools for the Deaf and Dumb, ncoats Hospital and Ardwick and Ancoats Dispensary, and e Hospital for Consumption, Hardman-street, Manchester.

London (R.F.H.) School of Medicine for omen.—The following scholarships have been awarded for e session 1923–1924: Fishmongers' Exhibition for Girls 50 a year for 3 years): Miss Winifred Harris (L.S.M.W.). stock Scholarship (£90 for 4 years): Miss Alice Hodge .S.M.W.). St. Dunstan's Medical Exhibition (£60 for or 5 years): Miss Joyce Woods (City of London Girls' hool). Mrs. George M. Smith Scholarship (£50 a year for years): Miss Kathleen Gambrell (Streatham Secondary hool). Dr. Margaret Todd Scholarship (£37 10s. for 4 years): iss Dorothy Wilkins, B.Sc. (Bedford College for Women). abel Sharman Crawford Scholarship (£20 for 4 years): iss Marguerite Fenn (L.S.M.W.). Sarah Holborn Scholar-ip (£20 for 5 years): Miss Ivy Varley (Newland High hool, Hull). Isabel Thorne Scholarship (£30): Miss ecima Tracey (Hamilton House, Tunbridge Wells). Dr. lith Poohey Phipson Post-Graduate Scholarship (£100 year for 1, 2, or 3 years): Dr. G. M. R. Webster.

Public Health Legislation in the Irish Free State.—On August 1st a deputation from the Irish Medical Committee waited on the Minister of Local Government (Mr. E. Blythe) to make certain representations to the Minister with regard to the Public Health Bill which, it is announced, will be brought forward in the Dail at an early date. The deputation urged the acceptance of the entire programme of the Irish Public Health Council, including the establishment of a Ministry of Health and of a National Medical Service, and discussed questions relating to the Poor-law Medical Service (inadequate salaries, arrangements for holidays, and fees for occasional services).

Medical Charitable Society for the West Riding of Yorkshire.—This society, founded in 1828, is one of the most flourishing of the societies connected with the medical profession. The annual subscription is one guinea, and those eligible for membership are medical men who at the period of their becoming members have not passed the age of 40, and have not been in practice in the West Riding more than 15 years without subscribing. From time to time the society has given in grants a sum amounting very nearly to £80,000; its investments have a nominal value of £43,374. The year from July 1st, 1922, to June 30th, 1923, began with a membership of 879. This number fell during the year to 853 in consequence of deaths and resignations, but was brought up to 897 by the election of new members, and the society now has a larger membership than ever before. Since the year 1911 the society has been administered under a trust deed. The work done by Dr. J. E. Eddison, who of late years has devoted much of his leisure to the work of the charity, is gratefully borne in mind by those connected with the society. No payment whatever is made to anyone connected with the work of the society, except to the professional auditors. Every request for assistance is closely scrutinised and sympathetically dealt with, and it is confidently claimed that no deserving case is ever passed over.

Appointments.

Marcus, Maurice, M.B., B.S. Lond., M.R.C.S., has been appointed Hon. Anæsthetist London Jewish Hospital.

Sandiland, E. L., M.B., B.S. Lond., D.P.H., M.R.C.S., L.R.C.P. Lond., Medical Superintendent of East Lancs Tuberculosis Colony, Cheshire.

Schuster, Norah, M.B., Ch.B., Pathologist to the Infants Hospital, Vincent-square, Westminster.

Manchester Royal Infirmary: **Stafford, H.**, M.B., Ch.B. Manch., Assistant Director of the Clinical Laboratory; **Smith, Eleanor P.**, M.B., Ch.B. Manch., Assistant Resident Medical Officer Central Branch.

St. Thomas's Hospital: **Dyson, A. D.**, M.R.C.S., L.R.C.P. Lond.; **Murrell, E. B.**, M.R.C.S., L.R.C.P. Lond.; **Cooper, G. K.**, M.B., B.Ch. Camb.; **Palmer, H. M.**, M.R.C.S., L.R.C.P. Lond.; **Lautre, M. A.**, M.R.C.S., L.R.C.P. Lond; **Lupton, C. A.**, M.R.C.S., L.R.C.P. Lond.; **Briggs, T. F.**, M.R.C.S., L.R.C.P. Lond.; **Williams, L. G.**, M.R.C.S., L.R.C.P. Lond., Casualty Officers and Resident Anæsthetists. **Story, A. G.**, M.R.C.S., L.R.C.P. Lond.; **Cole, L. B.**, M.B., B.Ch. Camb.; **Gibson, C. P. R.**, M.R.C.S., L.R.C.P. Lond.; **Fuller, C. B. S.**, M.B., B.Ch. Camb., Resident House Physicians. **Lund, G. S.**, M.R.C.S., L.R.C.P. Lond., Resident House Physician for Children. **Sudbury, F. B.**, M.R.C.S., L.R.C.P. Lond.; **Davies, D. A.**, M.R.C.S., L.R.C.P. Lond.; **Hughes, K. E. A.**, M.R.C.S., L.R.C.P. Lond.; **Crockford, A. L.**, M.B., B.Ch. Camb., Resident House Surgeons. **Wilkinson, M. C.**, M.R.C.S., L.R.C.P. Lond., Resident Orthopædic House Surgeon. **Kies, J. P.**, M.R.C.S., L.R.C.P. Lond.: **Walford, A. S. H.**, M.B., B.Ch. Camb., Resident House Surgeons for Ear, Nose, and Throat. **Berridge, W. C. M.**, M.R.C.S., L.R.C.P. Lond., Senior Obstetric House Physician; **Morrison, R. G.**, M.R.C.S., L.R.C.P. Lond., Junior Obstetric House Physician. **Doggart, J. H.**, M.R.C.S., L.R.C.P. Lond., Senior Ophthalmic House Surgeon; **Nicory, C.**, M.R.C.S., L.R.C.P. Lond., Junior Ophthalmic House Surgeon. A. F. **Potter**, M.R.C.S., L.R.C.P. Lond., R.M.O. St. Thomas's Home. **Hill, H. G.**, M.B. Camb., Senior Medical Casualty Officer. **Patrick, C. V.**, M.R.C.S., L.R.C.P. Lond., Senior Surgical Casualty Officer. **Cardell, J. D. M.**, M.B., B.S. Lond., Senior Resident Anæsthetist. **Cavenagh, J. B.**, M.B., B.Ch. Oxf.; **Neilson, D. F. A.**, F.R.C.S. Eng.; **Jones, B. H.**, M.R.C.S., L.R.C.P. Lond.; **Facey, R. V.**, M.R.C.S., L.R.C.P. Lond.; **Lockhart, L. P.**, M.R.C.S., L.R.C.P. Lond.; **Marriner, H. L.**, F.R.C.S. Edin.; **Hicks, E. W.**, L.M.S.S.A.; **Penman, G. G.**, M.R.C.S., L.R.C.P. Lond.; **Franklin, C. A. Manchester, St. Mary's Hospitals for Women and Children.—Two H.S.'s. Each £50.
Rotherham Hospital.—Sen. H.S. £260.
Royal Naval Medical Service.—Surgeon Lieutenants.
Staffordshire Education Committee.—Two Asst. School Med. Inspectors. £600.
Sutton, Surrey, Downs Hospital for Children.—Asst. M.O. £515.
Warwickshire, King Edward VII. Memorial Sanatorium, Hertford Hill, near Warwick.—Asst. Res. M.O. £350.
West African Medical Service.—M.O. £660.
West Riding County Council.—School Med. Inspector. £500.

The Secretary of State for the Home Department gives notice of vacancies for Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit Nos. 6, and 42 and 50 (St. Helens, &c., County Courts). Applications should reach the Private Secretary, Home Office, not later than August 25th.

Births, Marriages, and Deaths.

BIRTHS.

LIVINGSTON.—On August 2nd, at Wigmore-street, the wife of Flight-Lieut. P. C. Livingston, R.A.F. Medical Service, of a son (Clermont).

MARSHALL.—On August 3rd, at the Manor House, Goudhurst, Kent, the wife of R. Prynne Marshall, M.R.C.S., L.R.C.P., of a son.

PARKINSON.—On August 3rd, at 1, Devonshire-place, W. 1, the wife of John Parkinson, M.D., F.R.C.P., of a daughter.

MARRIAGES.

MARKLOVE—DAVIES.—On August 2nd, at the Parish Church, Stroud, John Carrington Marklove, M.R.C.S., L.R.C.P., to Muriel Alice Mary Davies, M.R.C.S., L.R.C.P., elder daughter of Mr. and Mrs. A. Barnes Davies, of The Old Vicarage, Stroud.

UNDERHILL—WORNUM.—On August 2nd, at All Souls' Church, Hampstead, Sydney William Frank Underhill, M.A., B.M., B.Ch., to Edith Betty, youngest daughter of the late G. Porter Wornum, Esq., L.R.C.P., M.R.C.S., and Mrs. Wornum, of Belsize-park, Hampstead.

DEATHS.

SMITH.—On August 5th, at 12, Clarence-road, Gorleston-on-Sea, Oliver Smith, M.B., Ch.B. Edin., aged 41 years.

STEWART.—On July 30th, suddenly, at his residence, Devonshire-road, Birkenhead, Andrew Stewart, L.R.C.P., L.R.C.S., in his 69th year.

WILKINSON.—On July 28th, at Portland-place, Leamington Spa, suddenly, Lancelot Craven Wilkinson, M.R.C.S., L.R.C.P., F.R.G.S., aged 43 years.

WILLIAMS.—On August 1st, at the County Hospital, Huntingdon, Frederick Edgar Williams, M.R.C.S., L.R.C.P., B.A. Camb., in his 61st year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SCHOLARSHIP IN MEDICINE.

BY SIR HENRY MORRIS, BART., M.A., M.B. LOND.

IN a letter to the *Times* on June 11th last, Mr. Gillbard alluded to the scientific, technical, and materialistic trend of medical education in the present day, and said that on that account a liberal and classical preliminary education for medical students is more than ever necessary. He told how Harvey, when in attendance on Charles the First at Edgehill, was found behind a hedge in the danger zone reading Virgil; and he grouped together Harvey, Sydenham, and Hunter as typical believers in the humanities. Two days later, Mr. George C. Peachey, in a letter also in the *Times*, (June 13th), took exception to the inclusion with Harvey of both Sydenham and "John" Hunter, as examples of the effect of classical education upon the progress of medical science—a selection which, he thinks, singularly unhappy.

In regard to Sydenham, who published a number of his works in the Latin language, there has been a considerable amount of discussion as to whether he wrote them originally in Latin or in English and got them translated into Latin. In regard to Hunter, Mr. Gillbard, in mentioning him, did not say "John" Hunter, who, it is true, had no classical education at all, and little general education of any kind. The Hunter to whom Mr. Gillbard referred, was, no doubt, John Hunter's brother, Dr. William Hunter, a man of great culture and learning, whose fine library of Greek and Latin classics, and whose extensive collections of natural history and other specimens passed to, and are now the property of, the University of Glasgow.

Francis Adams, M.R.C.S. Eng.

But the chief interest of Mr. Peachey's letter lies in his revival of the memory of a certain country surgeon, who lived and died a general practitioner in a small village on Deeside, and whose name is now almost forgotten, though it is but 62 years since his death. The name is that of Dr. Francis Adams, M.R.C.S. Eng., M.A. Aberdeen, and LL.D. Glasgow, of Banchory-Ternan, the editor and translator of Hippocrates, Paulus Ægineta, and Aretæus. Mr. Peachey spoke of Dr. Adams as "probably the greatest classical scholar among British medical practitioners of all time," and quoted some anonymous person who, in 1857, described him as "the most learned physician in Britain and probably in Europe."

Beyond question Dr. Adams was a great scholar, who possessed a most accurate and extensive acquaintance with the language and literature of Greece, and he ought to be remembered with special pride, and for all time, by those who practise medicine, as one whose classical attainments and competent knowledge of the French and German languages caused him to stand out prominently during life as a scholar, and enabled him to leave behind him writings which should make his name for ever famous. His translation of the "genuine" Hippocratic treatises is the only complete one in the English language; the same is true of his translation of the seven books of Paulus Ægineta, and of the treatise of diseases by Aretæus, the Cappadocian, one of the most celebrated of the ancient Greek physicians, and who is noticeable because of his dissension from the teaching of Hippocrates when he thought it imperfect or incorrect. By these translations, Adams did as great a service to those members of the medical profession who are not great Greek scholars, as Jacques Amyot (1513–93) did for the general run of French readers by his numerous translations of Greek literature and, especially, by his translation of Plutarch's "Lives" from the Greek into French; and as an English translation of the "Lives" was afterwards made from the French edition, Amyot's dissemination of Greek literature had its effect upon English prose, as well as upon French.

Adams should have a Memorial in the Royal College of Surgeons.

But Adams's claim to distinction is not merely that of a translator of concise and often obscurely expressed Greek treatises, such as those of Hippocrates, but because of the care with which he examined for himself the passages in ancient authors bearing on points open to discussion, and of his erudite "*preliminary discourse*" on the Hippocratic treatises, and the innumerable annotations and references throughout that work. He is said to have made himself acquainted with every extant Greek writing, not Greek medical writings only; and there is ample proof throughout this translation of Hippocrates, of his wide knowledge of Oriental, English, and European commentators and historians who have discussed the works of Hippocrates.

The period at which Hippocrates was practising his pro-ssion was "one of the most memorable epochs in the intel-ctual development of the human race," and Adams shows a miliarity also with the lives of all the great statesmen, tists, and scholars of that time. Indeed, Adams's erudition as so remarkable, and was developed so largely amidst the terruptions and distractions of medical practice, that there ight to be a bust or some other form of memorial of him in le Royal College of Surgeons of England, to mark the onour he is to his College, and to record the extraordinary egree of literary culture to which he attained whilst scharging to the full the duties of a general medical actitioner.

But notwithstanding the truth of the above appreciation Adams's erudition, some consideration of others ought to be iown before accepting off hand the title accorded to Adams y the *Medical Times and Gazette* (1861) of "Doctissimus ritannorum," and more especially before we claim for him le position of the most learned physician in Europe.

Linacre and Rabelais.

In this connexion something requires to be said about inacre for England, and Rabelais for France. Linacre 460–1524) lived at a critical period in the history of learning, hen the world was entering on a crisis, passing from the ediævalism of the schoolmen to the wider culture of le "New Learning." Rabelais (1495–1535) came somewhat ter, but was one of the most notable writers and thinkers the early days of the French Renaissance. Linacre had ceived an incentive to the study of Greek at the Cathedral hool at Canterbury, and, after election to a Fellowship All Souls' College, Oxford, he, with Colet (1467–1519) and few other Oxford scholars visited Italy, in 1493, and there came imbued with the learning and spirit of the Italian enaissance. England was a long way behind France and ill further behind Italy in exorcising the old conditions of ediævalism and introducing the humanities of the Renais-nce; but in Paris, on their way back to Oxford, Linacre d Colet came into touch with the two men who were preme in their influence upon European scholarship in the tter part of the fifteenth century and the first half of the cteenth century. These two men were Guillaume Budé udæus) and Erasmus, who were exact contemporaries of le another, having been born in 1466–67.

France had now gone ahead of Italy and become the centre European Greek culture and literature; and foremost in ance was Budæus, a Frenchman and a teacher of Greek in e University of Paris, who became the most famous an in Europe as an author on Greek philology, Roman law, d on education generally. Erasmus, the Dutchman, hose scholarly genius was developed in France, was the ly rival of Budæus, but was not his equal in Greek, though perior to him in style in the writing of Latin. Linacre and let formed ties of close friendship with these two men, upon iom in turn they exercised a marked influence; and on eir own part, by their eager study of Greek, they not only uminated the darkness which prevailed in England in the riod preceding the English Renaissance, and took the lead the revival of classical literature and the humanistic ovement in England in the Tudor period, but made some pression on contemporary European culture, in which nacre and Sir Thomas More, especially, played distin-ished parts.

Budé's influence on Colet was great and, under the zeal for ucational reform which he had imbibed from him, Colet unded, or re-founded and enlarged St. Paul's School in ndon for the study of Greek, as well as Latin.

Linacre also had a great regard for Budé and, in a letter ll extant, paid him a very high tribute of admiration. asmus, it is said, was one of Linacre's pupils in Greek, hers being Sir Thomas More, Prince Arthur, and Queen ary. Linacre closely studied the investigations of Aristotle d other Greek inquirers in natural science; he finally ncentrated his attention on the study of Greek medicine, d by translating the Greek works of Galen into Latin he quired Continental fame and spread widely the knowledge Greek medical literature. At home he founded the Royal llege of Physicians of London, and thereby did much ectly to organise the medical profession in England. nacre, like William Lily, the first Master of St. Paul's hool which Colet had re-founded, wrote a Latin Grammar iich obtained a great reputation abroad, and was very pular both with teachers and pupils on the Continent, as ll as at home.

No other classical scholar in British medicine has ever ercised so deep and wide an influence on classical literature d humanistic culture, outside his own country, as did nacre. In spite of the efforts of Linacre and Colet, how-er, Renaissance teaching was not to any great degree cepted by the English. This was shown by the coldness d indifference which More's "Utopia" met with in gland and the welcome given to its appearance on the ntinent.

Sir Thomas More's "Utopia."

Sir Thomas More (1478–1535), the author of the great political and social essay "Utopia," was 18 years younger than Linacre, and 11 or 12 years younger than Colet, Budæus, and Erasmus. When at Oxford, young More had Colet and Linacre for his tutors, and subsequently enjoyed the friendship and warm attachment of both Budé and Erasmus. But though it was through his circle of friends at Oxford that More was first smitten with the spirit of the "New Learning," it was his acquaintance with Erasmus—which began in 1498 or 1499—which caused him to return later with ardour to the study of Greek and the earnest pursuit of humanism. He published translations from the Greek and excelled beyond the average English scholars in writing Latin. His "Utopia," which was written in Latin and published in 1516, first at Louvain and then in Paris, was a contribution to European rather than to English literature. Through the kindly influence of Budé and Erasmus, "Utopia" took a prominent place in France, and edition after edition in the original Latin was issued from the Continental press. It was not translated into English until 35 years (1551) after it was first published in Latin, and a French translation appeared some time before it was rendered into its author's native language.

More's Influence on Rabelais.

A very notable feature of More's "Utopia" was the deep interest it aroused in Rabelais and the familiarity with its contents which is shown by Rabelais in his celebrated work, "Gargantua and his giant son, Pantagruel." Rabelais was greatly indebted to More. It would not be in place here to describe the similarity between Rabelais's story and More's political and social romance; but it is worthy of mention when passing on to consider Rabelais's reputation as a physician. I have on a previous occasion, in the columns of THE LANCET (1910, vol. i., p. 1155), written of this side of Rabelais's life, and if I again allude to it now, it is to speak of his scholarship in relation to his comparative eminence in medicine. Until the end of the fifteenth century, Greek was not known in France, but in 1495, the year of Rabelais's birth, a small coterie of scholars, including two physicians, was formed in Paris for the express study of Greek. Rabelais had previously studied Greek under difficulties, but when 25 years of age he got into communication with several members of this coterie, and with Erasmus, the leading scholar in Europe. One consequence of his acquiring Greek was that when lecturing in Montpellier, Rabelais was able to base his lectures on the Greek original of Galen, and on his own copy of the ancient manuscript of Hippocrates, instead of upon the mutilated and imperfect Latin translations used by former professors.

Rabelais had been a medical student in Paris and took his degrees in medicine in Montpellier in 1530 and 1537. He gave anatomical demonstrations on the human body both in Montpellier and Lyons, he invented certain surgical instruments, and with the sanction of the Holy Father, he was allowed to practise the art of Medicine for Charity, not for gain, and without using either the cautery or the knife. He was described by a contemporary as the "honour and sure glory of the healing art," and a Latin ode was written about him, in which it was said that by his skill he was esteemed the most eminent physician in France. But the renown of both Linacre and Rabelais, though eminent as practitioners of medicine, rests especially upon the distinction they acquired in general culture and classical literature, and upon their influence in promoting the "New Learning" throughout the civilised world.

FEMININE PSYCHOLOGY.

A WORK demanding that woman, unfitted for anything else by her manifold vices and imperfections, must have her powers curtailed and be restricted to the exercise of her reproductive functions, is something of an anachronism. That her vices result from a biological need is Mr. Ludovici's[1] vindication of her, and the vices are fully and feelingly described. The author writes in the style of the author of "Lovely Woman," but, unlike Mr. Crosland, takes himself seriously; so seriously, indeed, that he regresses to that primitive phantasy which psychologists call "the omnipotence of thought." What he thinks ought to be, is. Fertilisation is a natural process in woman; its absence leads to physiological disappointment, which "sings in chorus with the psychical disillusionment"; then she seeks a co-respondent; hence follows the frequency of divorce. The author thinks this ought to happen, so it happens. The control of conception ought to be harmful, so in the man "ultimate anæsthesia is inevitable." The thesis requires that woman should be unfit for sports; unfit she is, especially during her "moments of indisposition," and her violent sports, by a round-about pathology, lead to "very obscure but severe nervous disorders in later life." Perhaps the account of this last para-physical process only indicates an unquestioning belief in grandmotherly doctrine, and one comes to think that the author's attitude is a defence against the feminine in his own make-up, especially when he tells us (p. 352) that "it is enormously difficult for a woman to divorce her wishes, her likes and dislikes, from her beliefs and from her conclusions."

---

[1] Woman: A Vindication. By Anthony M. Ludovici. London: Constable. 1923. Pp. 378. 12s.

After a talk on the national downfall that is about to follow the growth of feminism, the author says, "We cannot now with any pretence of honesty or good faith claim that it is a plunge into the unknown." This tribute to the physical reality of the phantasy concludes a book that is not so startling as the picture on the wrapper would indicate.

"THE FIGHT AGAINST DISEASE."

THE July issue of this little journal, published by the Research Defence Society at the price of 6*d*., and sold by Macmillan and Co., Ltd. (St. Martin's-street, London, W.C. 2.), contains the accounts and the Committee's annual report, signed by Lord Knutsford as chairman, together with pithy notes on the world's health, and illustrated articles regarding small-pox at Gloucester and in the United States (with a letter from Prof. Keen of Philadelphia), and tuberculosis treated by heliotherapy in Switzerland. Its pages are few but piquant.

POPULAR ENDOCRINOLOGY.

IN a scholarly little book on "Ductless and Other Glands," recently published (George Allen and Unwin. 4*s*. 6*d*.) Dr. Fred. E. Wynne, the versatile medical officer of health for Sheffield, gives a popular description of the results of recent endocrine research and the application of this knowledge to the prevention and cure of disease. Thyroid, parathyroid, thymus, suprarenal, pituitary and pineal are taken in succession and their secrets laid bare. Finally, Dr. Wynne deals with the ability of extracts of glands to renew the youth of man. In spite of the work of Voronoff on monkey glands, he warns the reader only to accept such conclusions on overwhelming evidence. The cycle of growth, maturity, and decay is a law of nature that governs suns and solar systems, as well as the protoplasm that crawls and swings for a time on the surface of this little planet. Man's only demonstrable immortality is his power to beget and transmit his qualities to his offspring. Dr. Wynne concludes that if youth and maturity were rightly used, if social conditions were what they might be made, old age would be as physiological a period as any other, and probably no less pleasant, a tranquil preparation for a welcome cessation of consciousness.

PUBLIC HEALTH IN NIGERIA.

Mr. A. C. Burns, assistant secretary at Lagos, is responsible for the annual general report for 1922 on the Colony and Protectorate of Nigeria, situated on the northern shores of the Gulf of Guinea. According to this report the general health was good throughout the year, the gravest problem presented during the period being a recrudescence of cerebrospinal fever in epidemic form. The outbreak declared itself in the north-eastern region of the Kontagora Province—i.e., immediately south of the eastern limit of the epidemic of the previous year. At first its aspect was gravely menacing, but all available precautions were taken, and, in the end, the advent of the rains found it happily still localised within the region of recrudescence, wherein it finally subsided. In the autumn the Emir of Katsina reported its existence in the French territory across his northern boundary, but the end of the year left Nigeria free from the visitation. A "health week" was organised in Lagos in November, and prizes were offered for the healthiest babies and the best-kept compounds. The people were much interested, and an immense quantity of accumulated refuse was disposed of during the week. The population of Nigeria is approximately about 18¾ millions—larger than that of any British dependency except India. There are about 4000 Europeans temporarily resident in Nigeria, chiefly in the employ of the Government, and of mercantile and mining companies. The country is not suited for European settlement. Of the native inhabitants the greater number are of pure negro race, but in the north there are Berber and negroid tribes. The seasons in Nigeria depend rather on the rainfall than on temperature. They are, as a rule, well defined. The dry season, with its attendant "harmattan," commences in the north of the country in October and ends in April. It is of shorter duration in the south, and at Lagos generally lasts from November to March with only intermittent "harmattan." During the "harmattan" (a dry north-easterly wind which brings with it a thick haze composed of minute particles of dust and shell) the nights and early mornings are cold, but the days are very hot, and it is during this period that the maximum diurnal variations occur. Under the heading "General Observations," in Mr. Burns's report, we find the following: "One of the principal religious obstacles to the advance of Christianity in tropical Africa is the prevalence and popularity of polygamy. Among the followers of Islam this institution has, of course, the sanction of religion. Among the non-Muslim tribes it has the equally strong sanction of immemorial custom. In West Africa children are assets rather than liabilities, the daughters being easily marketable as wives at an early age and the sons providing an unpaid labour supply; wives, besides their value as mothers, perform most of the manual labour in the house and on the family farms, but the custom which requires a mother to deny herself to her husband for the period during which she is nursing her child, often from two to three years, is, perhaps, the greatest cause of polygamy. The Native African Church, modelled in other respects on the Church of England, but allowing to its members a plurality of wives, has met the difficulty of those who wished to adopt the Christian Creed without abandoning one of the most cherished of their ancestral customs."

THE PEKING UNION MEDICAL COLLEGE.

THE Peking Medical College grew out of a small dispensary, originally founded at Peking by William Lockhart, of the London Missionary Society, in 1861. The work slowly progressed until the time of the Boxer rising, when all the buildings and plant were destroyed. After the rising, work was begun again in 1906, and various other missionary societies, both British and American, joined together to found the Union Medical College. This College continued to grow until 1914, when the Rockefeller Foundation despatched its Commission to China to study the question of medical education there. As a result the China Medical Board purchased the entire plant and arranged for the complete reorganisation of the school under charter from the University of the State of New York. A volume[1] recently published describes the ceremonies and the conference held in September, 1921, being some 60 years since the foundation of the first medical mission in Peking in 1861.

The College is equipped with the very latest apparatus and plant necessary, not only for the treatment of patients, but also for medical education and research. It is apparently doing admirable work, and, as medicine seems to be the one subject upon which men of all creeds and nationalities can agree, its activities should go far towards bringing about that union between nations in which the hope of the world lies to-day.

A Critical Investigation
INTO THE
HERMAL DEATH-POINT OF THE TUBERCLE BACILLUS IN MILK,
WITH SPECIAL REFERENCE TO ITS APPLICATION TO PRACTICAL PASTEURISATION.

BY F. W. CAMPBELL BROWN, M.D.,
CH.B. ABERD., D.P.H.,
TE SENIOR ASSISTANT LECTURER AND CARNEGIE RESEARCH SCHOLAR, UNIVERSITY OF ABERDEEN.

THE thermal death-point of the tubercle bacillus milk is a question to which many workers have ven answers, but so discrepant have been the results at it would appear necessary that this work be vised and any possible previous sources of error minated by strict observance of care throughout e experiments. Further, it would appear neces-ry to have more definite results when one takes to consideration the prevalence of bovine tuber-losis among human beings at the present day—the ajority of all such infections being transmitted by e milk of tuberculous cows. Milk-borne epidemics of phoid, dysentery, &c., are not only historical facts, it also present-day occurrences, and neither the lation of "carriers," nor the application of the ost recent methods for early diagnosis of infectious sease amongst cows and milk workers will make e danger of milk-borne epidemics a thing unheard . Considerations such as the above have led to the lief that a further attempt should be made to tain information which would help to render such universally used and essential food [illegible] milk a less ngerous article for consumption in human dietary. Beneficial methods of treatment other than steurisation have been devised and used to render lk sterile. The addition of preservatives—e.g., ric acid, &c.—was sometimes used, but this is not practice to be advocated. The quality of any such eventive required to destroy the tubercle bacillus milk would be harmful to the tissues of the human dy. Boiling the milk would in all probability stroy the tubercle bacillus, but in this case certain rmal constituents of the milk are destroyed, and thout these such milk becomes a much less valuable ticle of diet than in its fresh state. Electrical ethods are being adopted in America and in Liver-ol with some degree of success. This is an expen-e method of treatment, and it has been shown that is not any action peculiar to the electric current hich sterilises the milk. Rather the action is due the heat set up by the electricity [illegible] it flows through e apparatus.

The question of attacking the bovine tuberculosis the human being at its source—i.e., in the cow—has en receiving much attention in recent years. The plication of the tuberculin test, the better super-sion of byres, and other factors which lead to althy non-tuberculous herds, are all steps in the ght direction; but to rid the country of all its berculous cattle is going to take [illegible] considerable ne, and will require more stringent legislation than at present in force. Even although tubercle-free rds have been installed throughout the country, steurisation will still remain as the best safe-ard for getting rid of other contamination from irces other than the cow.

With these points in view, it will be necessary to nsider the question of the thermal death-point of e tubercle bacillus from every possible angle to able one to say that the pasteurisation process ed is of decided value. The results obtained by evious workers must be noted and their methods refully considered from the practical point of view.

EVIOUS ATTEMPTS TO DETERMINE THE THERMAL DEATH-POINT OF TUBERCLE AND OTHER BACILLI.

At varying periods numerous workers have added eir names to the now long list of investigators on this subject, giving, for the temperature factor 60° C., time factors varying from five minutes to eight hours as the necessary exposure of the bacilli to that degree of heat in order to destroy them. Many attempts have also been made to state [illegible] time factor when the temperature used was 70° C., but here, again, the results recorded are widely conflicting, varying from 1 to 45 minutes' exposure. Table A is [illegible] list (taken from Delépine's Food Report No. 79) of results obtained by various workers who used 60° C. and 70° C. [illegible] the temperature factors—the temperatures used also in the writer's experiments.

TABLE A.

Investigator.	Temperature used.	Time found necessary to kill the bacillus.
Yersin (1888)	60° C.	10 mins.
Bitter (1890)	,,	5 mins. sometimes enfeebles.
Bonloff (1892)	,,	20 mins.
Forster (1892)	,,	6 hours.
De Man (1893)	,,	1 hour.
Schraeder (1894)	,,	15 mins.
Woodhead (1895)	,,	(*a*) 8 hours (*b*) 45 mins.
Theobald Smith (1899) ..	,,	15–20 mins.
Russell and Hastings (1900)	,,	20 mins.
Hesse (1901)	,,	20 mins.
Rosenau (1907)	,,	20 mins
Delépine (1914)	64°–92° C.	Not killed in 39 mins.
Bang (1891)	70° C.	5 mins. only enfeebles.
Grancher and Lideux-Lebard (1892)	,,	1 min.
Woodhead (1895)	,,	(*a*) 45 mins. (*b*) 1½ mins.
Morgenroth (1900) ..	,,	10 mins.
Russell and Hastings (1900)	71° C.	1 min.

POSSIBLE CAUSES OF VARYING RESULTS PREVIOUSLY RECORDED.

(*a*) The tubercle bacillus may vary in different cases in its resistance to heat; and in order to get over this difficulty, it is essential that as large a number of different strains as available be tested. Rosenau used five different strains in his experiments, whereas Delépine used milk infected by one animal to which cultures of another strain were added, thus having a mixture of only two strains.

(*b*) Variation of results may also be due to: (1) The fact that the only way to determine whether tubercle bacilli are alive or not after pasteurisation is by animal inoculation, necessitating much delay for obtaining results; (2) the difficulty in some cases in differentiating a lesion seen at post-mortem resulting from dead bacilli from that due to live bacilli; (3) the fact that somewhat similar post-mortem appearances are produced by pseudo-tuberculous lesions, caused by an entirely different organism. Only by searching for acid-fast bacilli can [illegible] differentiation be made in such cases.

(*c*) There is also the difficulty in obtaining standard and uniform dosage of bacilli for the animals—it being a well-known fact that the extent and rapidity of spread of the disease depend to some extent on the numbers of bacilli injected. Again, the period of time which elapsed before the animals were inoculated and examined may not have been uniform; and this is important, [illegible] Delépine points out that the disease produced by heated bacilli remained latent or occult for some four weeks in his set of experiments. Unless sufficient time elapses before the animals are examined, latent lesions may be missed. This point is brought out in Tables II. and III. of his report.

(*d*) The method of arriving at the exact temperature of the infected milk must essentially be taken into account. In all pasteurising plants the milk is *rapidly* raised to the desired temperature, the time taken being only a few seconds.

In the laboratory it is difficult to do this. The time required to raise the infected milk to the requisite temperature is much longer. The organisms are consequently being exposed to the slowly increasing temperature of the milk while the experimenter is waiting for it to reach the desired 60° C. at which the exposure factor comes into play. I am of the opinion that, because the bacilli are being subjected to, say, 50° C. to 60° C. for a variable period, some may be killed, and all to an extent enfeebled, before the temperature of the milk reaches 60° C. In Rosenau's experiments, the bacilli were added to the cold milk and received a critical heat during the time the milk was being raised to 60° C. before the time factor was taken into account.

(*e*) Further, the method of maintaining a uniform temperature of 60° C. throughout the test, and recording the same, must be provided for. In both these points (*d*) and (*e*), Delépine's experiments cannot be truthfully compared with those of Rosenau's. The temperature used in Delépine's tests was a steadily rising one. On page 41 of his report, the words "the heating of milk from 12° to 78° in 29 minutes" do not agree with the figures given for time and temperature on page 6, and to which the paragraph on page 41 evidently refers. According to the figures on page 6, the time taken to raise the mixture from 12° to 78° was *19 minutes.* The milk remained at or above 60° for only seven minutes, when his sample (3) was taken at 78° and found to contain living bacilli. He also goes on to state in the same paragraph that after ten minutes more the sample (4) taken was found infective. The mixture had not 20 minutes' exposure to heat at or above 60° when this sample was taken, but only 18 minutes. He had no further sample taken for 72 minutes after this, and this was found sterile. His statement, therefore, cannot be correctly used to disprove Rosenau's belief—i.e., that tubercle bacilli are killed in 20 minutes at 60° C.

(*f*) Perhaps of all the possible causes for these varying results the most important is the container used, in which the test milk has been pasteurised; and it is only comparatively recently that more exact methods have been employed. It has been usual for the investigator to heat the infected milk in test-tubes, which were then immersed in a hot water-bath standing at a regulated temperature. With such a method there are two possible sources of error. Firstly, the test-tubes being open to the atmosphere, a surface scum forms on the milk. Bacilli find in this scum a certain degree of refuge from the heat, and a scum such as this will not maintain the same degree of heat as the deeper portions of milk, which will always be in circulation. Smith found that when no scum was allowed to form on the surface of the heated milk, as by heating it in closed vessels, tubercle bacilli were killed at 60° C. in 15 minutes, whereas when a pellicle was allowed to form these organisms survived for one hour at the same temperature. Secondly, there is the obvious danger of splashing the sides of the tube with live bacilli, which may quite easily contaminate the pipettes used for withdrawing later samples, when the bacilli withdrawn from the fully heated portion of the milk are by that time killed. And a further objection is that, by capillary attraction and by withdrawing sample after sample, a film of infected milk is left on the interior walls of the test-tube above the milk level. The inevitable result must be that numerous bacilli escape the full heat for a varying period, and tend slowly to fall by gravity into the bulk of milk, only to reinfect it after it might otherwise have been rendered sterile.

This appears to be the drawback to Rosenau's method, which was that described above. So also Twiss used an open flask when she carried out similar tests, using paratyphoid bacilli in her experiments. Her conclusion—i.e., that the results got by taking small amounts of test samples cannot be taken as proof that all the organisms are killed after periods of exposure used in practical pasteurisation—would appear to be due to the fact that a few organisms remain unexposed to the heat. These are not removed in the small amounts taken for inoculation of "sugars" or animals as the case may be. This vital point has been commented upon by Krumwiede and Noble, who repeated this work. These investigator made a distinct step forward when they adopted th plan of *totally immersing* the milk sample containe in the water-bath, thus ensuring that all organism present were exposed to the required degree of hea for the required period of time. In their exper ments, measured quantities of sterile milk wer placed in separate containers, submerged in a water bath till the temperature of the milk reached 60° C and then the emulsions of organisms were added Each container with a rubber stopper was the *totally* immersed in the water, removed after a pre determined time, and immediately cooled.

This method undoubtedly has distinct advantage over the open test-tube method, but it is not fre from comment. The technique is good, but require finer detail in order to get absolutely correct an uniform results. First, there is no method of registering the temperature of the milk throughout th experiment. Krumwiede and Noble make no mention of having a thermometer inserted through th rubber cork of the containers. The necessity for thi is borne out by the fact that, when I originall thought of employing similar methods in the following tests, I found that by inserting a thermomete through the stopper and placing the container o the bottom of the hot water oven and totally immersing it, the temperature of the fluid inside the container exceeded that of the water bath by 2·5-3 as a rule. On one occasion it was actually 10 warmer. It was not until after many attempts ha been made to explain this anomaly that it was foun to be due to the fact of the container resting on th metal bottom of the bath, which was warmer tha the water. (The bath was heated from below by gas jet.) On the other hand, if the container wa *suspended* in the water and just clear of the botton of the bath, the temperature inside the containe coincided with that of the water in the water-bath And, further, Krumwiede and Noble make no mention as to whether or not they provided for a lowerin of the temperature of the milk standing at 60° C when the emulsion of bacilli, presumably at roon temperature, was added.

The necessity for guarding against this lowerin of temperature was borne out by the writer addin 1 c.cm. of emulsion at 37° C. to 5 c.cm. milk standin at 60° C. The result was that the temperature o the milk emulsion at once dropped 7–8° C. And it was several minutes before the temperature of the infected milk rose to the figure (60° C.) at which the time factor comes into play. More especially is thi to be considered when results are to be given in suc short periods as minute intervals. It is, therefore necessary before exact exposure periods can be obtained that certain preliminary adjustments be made to the apparatus and temperatures used before beginning any tests on the thermal death-point of any micro-organism. In my experiments such preliminary data were carefully prepared for use with a specially-made apparatus for subjecting infected milk to the degree of heat to be used. These, and the apparatus, will be later described in detail.

Methods Used in Personal Experiments.

The various cultures of tubercle bacilli used in the following experiments were obtained in the majority of cases from tuberculous ox glands, tuberculous milk, human tuberculous sputa, tuberculous joints and bones in man, &c. In addition, a few cultures were obtained from France, Germany, and the United States of America in order to ascertain whether a more resistant type of the tubercle bacillus existed in countries whence cattle are exported for use as human food in the United Kingdom. In all, 35 different sources were used for obtaining strains, some of which might possibly be more virulent or have a greater resistance to heat than the others. All those used were obtained since January, 1921, none being over eight months old, and the majority very much less.

Many weeks were spent in trying to isolate pure cultures from the tuberculous material obtained, and was not ascertained till numerous attempts had een made by the antiformin method advocated by [uir and Ritchie that the chlorine content of the ntiformin varied with different supplies. It became vident that little or no success was likely to be btained by this method, and the more recent technique, as used by Griffith, was employed, and with uch greater success. In this method it matters ttle whether the chlorine content of the antiformin aries or not, as will be understood by the technique nployed by the writer. In this case 10 per cent. ntiformin solution was added to an equal volume the sputa, &c. The mixture was rapidly shaken, id single loopfuls were sown on to culture edium after varying lengths of time—e.g., after xposures of 1, 3, 5, 10, 15 and 30 minutes. In is way a point is reached when all extraneous rms are killed, and only the more resistant tubercle acilli remain alive. The most usual result found as that the culture tubes inoculated with tuberculous aterial exposed to the antiformin for less than five inutes were contaminated by the extraneous germs. n the other hand, pure growths of tubercle appeared either the 5, 10, or 15 (more usually the latter two) ilture tubes. Very rarely were any cultures btained from the tubes inoculated with sputum hich had been exposed to this percentage of antirmin for 30 minutes. With such a lengthy exposure e bacilli were evidently killed. In a few cases the acilli withstood this length of exposure to 10 per nt. antiformin; this was possibly due to the sputum ing thicker and more tenacious, as Griffith suggests. the case of ox glands, shorter exposure of the seous material was found to give the best growth media. Such material would appear to protect e tubercle bacilli to a less extent than does tenacious utum.

The only disadvantage in this method is the cessity of using six tubes of culture material for ch attempt instead of one or two. The time used, wever, is shorter than in the older method, where much use of the centrifuge for washing out the kaline antiformin after exposure to the tuberculous aterial is necessary. In order to utilise less culture edium small tubes were used for the primary owth, and from the one containing the pure growth bcultures were sown on large tubes in order to tain sufficiently abundant growths to perform the rther experiments.

The culture media used for obtaining growths were ther the egg medium advocated by Dorset, or a odification of the same. In some cases Petroff's edium was employed for the original attempts, iere pure growths were difficult to obtain, but it peared that the gentian violet as used somewhat nded to inhibit the tubercle bacilli as well as the ntaminating organisms. The best results, especially ien the method of sowing as used by Griffith as adopted, were obtained by using ordinary egg edium with sufficient quantity of basic fuchsin ded to colour the medium dark pink, as suggested Cruickshank. By using such a medium the eam-coloured early growth was more readily cognised than when no fuchsin was added. The dition of the fuchsin did not appear in any way inhibit the growth, which could be observed even seven days in most cases.

Glycerine was added according to whether the rticular strain being isolated was from a human or vine source, and it must be said that although in ore recent views it is held that this substance nnot be relied upon to differentiate between the man and bovine types of this bacillus, the vine strains did not grow at all, or at any te only grew very slowly, on glycerine egg. though this fact was noted, this method was t used for differentiating the various strains ed in this series of investigations. After several nths, during which nothing was done beyond perimenting with different media and obtaining a sufficient quantity of pure cultures, the tal number of cultures exceeded 250 in number. This stock consisted of 35 strains obtained from different sources.

PREPARATION OF INFECTED MILK FOR PASTEURISATION EXPERIMENTS.

An emulsion of 0·2 g. dried bacilli and 1 c.cm. sterile milk was added to 5 c.cm. milk at a temperature of 67° C. in a specially designed flask. The flask was devised so that a thermometer could be kept in its interior. It had also a thin limb with a stopcock at the extremity for withdrawing samples of milk by means of a pipette at various stages of the experiments. The entire apparatus was kept completely submerged in a water-bath standing at 60° C., and only the stop-cock withdrawn momentarily when a sample was required. The effect of adding 1 c.cm. emulsion at room temperature was to lower that of the 5 c.cm. from 67° to 60° C. immediately, thereby enabling the experiment to be commenced at the temperature desired for the duration of the test. This precaution seems to have been overlooked by numerous workers, and would appear to be necessary, especially when the more delicate organisms are being dealt with. The samples withdrawn were of uniform quantity, quickly cooled to 30° C., and then inoculated into guinea-pigs, each pig receiving 0·02 g. tubercle bacilli in 1 c.cm. milk. Heavy infection was aimed at to ensure quick and decisive results.

In all, 25 strains of tubercle bacilli were tested in this manner, ten samples being taken at varying exposure times, and an unheated sample inoculated as a control for each strain. In order to ascertain whether or not all the bacilli were killed and none remained unexposed (in the apparatus) to the heat, organisms giving more rapid reactions than tubercle bacilli were used. That no live bacilli had escaped inclusion in the samples was proved by inoculating the whole flask and its remaining contents in suitable culture media.

INOCULATION OF TEST ANIMALS.

The guinea-pigs were inoculated at the flexure of the thigh, and each series was isolated from those used for the different experiments. No animal was killed before the tenth week after inoculation, in order to allow time for latent disease to become manifest, and in cases of doubt reinoculation with the doubtful lesions were made. The presence of the disease in the positive animals was in most cases quite definite, being made manifest by abscess-formation at the site of inoculation, enlargement of lymphatic glands, presence of tubercles or necrotic areas in the liver, spleen, lungs, &c.

RESULTS OBTAINED.

These are given in detail in the tables, which contain only a summary of the results obtained, and do not convey to the reader any idea of the vast amount of time and work spent in carrying out these experiments. The animals used, including those required for reinoculations, exceeded 280 in number; and the time taken in carrying out this part of the tests alone—i.e., in inoculating, supervising, and performing autopsies on them—extended over six months.

Tables I. and II. give all the results obtained with 15 bovine strains, using 60° C. as the temperature factor. It will be noted that in the great majority of cases ten minutes' exposure to this degree of heat is not sufficient to prevent the bacilli from causing tuberculosis in the guinea-pig, while even 15 minutes is not sufficient in some cases. However, a period of 20 minutes was found either to kill the bacilli or so to enfeeble them that the protective forces in the guinea-pig were able to prevent the latter from becoming tuberculous. Three strains, Nos. 3, 7, and 12, gave rather doubtful results after 20 minutes' exposure, but on reinoculation with the doubtful lesions no tuberculosis developed in any of the animals used. It was unfortunate that the control animal for strain No. 13 died accidentally, but the fact that the animals given this strain heated for 10 and 15 minutes developed tuberculosis proves that the strain was [illegible] virulent one, and it has therefore been included with the others in Table I.

TABLE I. (BOVINE STRAINS).—*Infected Milk subjected to 60° C. for Varying Exposures as stated below.*

Strain	C	Time of exposure at 60° C. (in min.)					Strain	C	Time of exposure at 60° C. (in min.)				
		10	15	20	25	30			10	15	20	25	30

C, Control animal. +, Tuberculosis found at autopsy.
–, No tuberculosis found at autopsy.

Result.—All rendered non-lethal at or before 20 minutes' exposure to 60° C. Refer to Table II. for doubtful cases.

TABLE II.—*Confirmation Tests from Doubtful Lesions of Guinea-pigs in Table I.*

Strain.	Lesion from animal treated with milk at 60° C. for :—	Guinea-pig.	Guinea-pig.
3	20 minutes	–	–
7	15 ,,	–	–
7	20 ,,	–	–
12	20 ,,	–	–

Result.—Doubtful lesions as recorded in Table I. were found to be caused not by living but possibly by dead bacilli.

TABLE III. (BOVINE STRAINS).—*Infected Milk subjected to 70° C. for Varying Exposures as stated.*

Strain	C	Time of exposure at 70° C. (in min.)					Strain	C	Time of exposure to 70° C. (in min.)				
		1	3	5	10	15			1	3	5	10	15
1	+	+	+	–	–	–	9	+	–	–	–	–	–
2	+	–	–	–	–	–	10	+	+	–	–	–	–
3	+	+	–	–	–	–	11	+	+	–	–	–	–
4	+	+	–	–	–	–	12	+	+	+	–	–	–
5	+	+	–	–	–	–	13	+	+	+	–	–	–
6	+	–	–	–			14	+	+	–	–	–	–
7	+	+	+	–	–	–	15	+	–	–	–	–	–
8	+	–	–	–	–	–							

Result.—No virulent bacilli were found after 5 minutes' exposure to 70° C.

Table III. gives the results when the infected milk [illegible] heated at 70° C., using the same 15 strains of bovine tubercle bacilli. In this case no tuberculous lesions developed in any of the animals inoculated with infected milk which had been exposed to a temperature of 70° C. for five minutes. While the essential object of these tests is to determine the thermal death-point of the bovine type—the type which is most likely to be found in cow's milk—yet it should be borne in mind that there is always the possibility of contamination of milk by the human type of the bacillus. Contamination with the latter may occur from tuberculous dairymen. It is important, therefore, that the thermal death-point of the human type also be ascertained. For this purpose ten human strains were tested, and the results obtained are given in Tables IV. and V. It will be observed that there would appear to be little or no difference in the thermal death-point between the bovine and human types of this organism.

I believe that, when tuberculous milk is *heated either at 60° C. for 20 minutes or at 70° C. for 5 minutes, it can safely be assumed that the bacilli are killed.* If they are not actually killed, they are so enfeebled that the normal powers of resistance of the guinea-pig find the former an easy prey, and no tuberculosis develops. This statement can in all probability be applied to man. More especially is this the case when it is not to be expected that the milk he drinks would ever contain such numbers of bacilli as have been given to the guinea-pigs, each guinea-pig receiving 0·02 g of pure culture as a dose. Therefore, *tuberculou infection* from milk treated with either of these tw combinations of temperature and time factors ma be entirely disregarded from an administrative publi health point of view.

TABLE IV. (HUMAN STRAINS).—*Milk Infected whe at 67° C. and Mixture kept at 60° C. througho Exposure Periods.*

Strain	C	Time of exposure to 60° C. (in min.)					Strain	C	Time of exposure to 60° C. (in min.				
		10	15	20	25	30			10	15	20	25	3
1	+	+	–	–	–	–	6	+	+	–	–	–	–
2	+	–	–	–	–	–	7	+	+	–	–	–	–
3	+	+	–	–	–	–	8	+	+	+	–	–	–
4	+	–	–	–	–	–	9	+	–?	+	–?	–	–
5	+	–	–	–	–	–	10	+	+	–	–	–	–

Result.—In all cases an exposure of 20 minutes at 60° C. wa sufficient to render the bacilli non-virulent. Reinoculation doubtful results got with No. 9 proved negative.

TABLE V. (HUMAN STRAINS).—*Milk Infected when 77° C. and Mixture then kept at 70° C. througho Experiment.*

Strain	C	Time of exposure to 70° C. (in min.)					Strain	C	Time of exposure to 70° C. (in min.)				
		1	3	5	10	15			1	3	5	10	1
1	+	–	–	–	–	–	6	+	+	–	–	–	–
2	+	–	–	–	–	–	7	+	+	–	–	–	–
3	+	–	–	–	–	–	8	+	–	–	–	–	–
4	+	+	+	–	–	–	9	+	+	+	–	–	–
5	+	+	–	–	–	–	10	+	–	–	–	–	–

Result.—No virulent bacilli remained after 5 minutes' exposur to 70° C.

But because either method of treatment wi render milk free from infection, the effect of heat o the other constituents of the milk must not be disregarded; and it is now necessary to consider i both methods of treatment may produce equall good effects, or if there are sufficient grounds fo preferring one as opposed to the other.

There is evidence to show that the organism producing lactic acid in milk prevent the development of spore-forming organisms of the putrefactiv group. Therefore, the presence of the former in th treated milk is an advantage. Further, the effect o prolonged exposure to temperature exceeding 65° C has been shown to destroy valuable enzymes in th milk; and also the fat globules may be broken up and the "cream line" lost.

The question of the effect of heat on enzymes i milk has been studied by many workers, and th results obtained are given by Race. His result show that exposure to temperatures of 65° C. an under for a period of 30 minutes has no effect on th enzymes found in fresh milk. Numerous worker quote figures dealing with this question, but the mos recent and probably the most accurate authority o the subject is McCollum, who has done [illegible] muc valuable recent work on the nutritional value o various foodstuffs. The work of Hess and of McCollu together indicate that the effect of different degree of heat on the nutritional value of milk is extremel important in the consideration of scurvy in infant

Scurvy is considered by these workers as o bacterial origin, but the reasons cannot be gone int here. Sufficient it is to quote the conclusions com to by them. These are that milk heated to 74° C. fo 30 minutes is more liable to cause scurvy than mil which has been pasteurised at 63° C., or boiled. Th explanation given is that at 74° C. nearly all the lacti acid-forming bacilli are killed, and so the spore-formin bacilli alone remain, and in time bring about putrefactive decomposition. Further evidence is given t show that stale pasteurised milk augments the dange of development of scurvy in infants.

They further add that pasteurisation in itself does no seem to have any influence in lowering the nutritiv *lue of milk, but that pasteurisation should be carried t at the lowest temperature which will destroy the action pathogenic organisms, and the milk consumed soon ter treatment.*

With these facts in view it would, therefore, appear at the "flash" system as carried out in the majority dairies in this country is inferior to the "holding" stem, for the following reasons :—

(1) Exposure to 70° C. for a mere matter of a few conds does not destroy the action of the tubercle cillus.

(2) By killing the harmless lactic acid-forming cilli, the harmful putrefactive organisms are more adily allowed to develop ; and further—

(3) The fact that souring is prevented allows the lk to remain "sweet" to the housewife, whereas if our" it would not be used (vide ante—Scurvy).

(4) The possibility of the lactose becoming scorched, e casein hardened, and the calcium, magnesium, and osphoric salts precipitated, and also the commercial jection—viz., the "cream line" being interfered th.

As the "holding" system, using a temperature of ° C. and holding the milk thereat for at least 20 nutes, seems to have all the advantages and none of e disadvantages of the "flash" system, it is to be eferred.

CONCLUSIONS.

1. It has been shown that by using 25 strains of the bercle bacillus no wide difference in the thermal ath-point is found.

2. The thermal death-point of this organism is actically similar for human and bovine types.

3. The previous wide variations in results have en due to too little care in carrying out the experients, and to the fact that the lesions caused in test imals had not previously always been given sufficient ne to develop and be accurately diagnosed.

4. If a temperature of 60° C. be used, it requires minutes' exposure to this degree of heat to event milk so treated carrying infection to the inea-pig.

5. If a temperature of 70° C. be used, it requires five nutes' exposure to ensure the same results.

6. Of these two combinations of time and temperae factors, the former excels the latter, when the *d value* of the treated milk is also considered.

7. The writer is of opinion that, until bovine tuberosis can be stamped out at its source—namely, the ox—proper pasteurisation of milk is the only e method of rendering milk safe as a diet for nan consumption.

Vote.—Since the completion of these results in 1922 s interesting to note that, by the passing of the k and Dairies (Amendment) Act, 1922, and the ne of the Milk (Special Designations) Order, 1922, de by the Minister of Health under Section 3 of the 1 Act, *legislation now exists* whereby until July 1st, 3, any process of pasteurisation (including the ash" process) capable of effecting the necessary uction of bacteria was permitted. Subsequent to t date suppliers of pasteurised milk must conform certain conditions if the milk is to be sold as teurised milk. One of these conditions compares ourably with my results—namely, that the milk st be retained at a temperature of not less than ° F. (approx. 63° C.) and not more than 150° F. prox. 66° C.) for at least 30 minutes ; also that no er treatment of heat may be adopted. These its of temperature and duration of exposure give afe margin as far as ensuring the destruction of any ercle bacilli in milk thus treated.

ANTE-NATAL DIAGNOSIS.*

BY FRANCES M. HUXLEY. M.D., B.SC. MANCH.,
SENIOR ASSISTANT SURGEON, SOUTH LONDON HOSPITAL FOR WOMEN; LATE ANTE-NATAL PHYSICIAN,
QUEEN CHARLOTTE'S HOSPITAL.

THIS is a large subject, and I propose dealing with it strictly from the clinical point of view, laying stress on the methods by which a diagnosis is come to. With it is very closely associated the actual diagnosis of pregnancy itself. Success in diagnosis is based on a routine method of examination, and the recognition of abnormal conditions on a wide experience of the normal.

The patient should always be prepared by emptying the rectum and bladder. The latter can be a particular source of trouble. Conditions which hinder diagnosis are nervousness on the part of the patient, difficulty in adopting the abdominal type of breathing, stoutness, and unduly developed musculature of the abdominal wall. The results of nervousness can usually be obviated by paying attention to the history and by examining other parts, such as the breasts, before beginning to palpate the abdomen. None of the manipulations involved in making a complete diagnosis should hurt a normal patient. Gentleness and patience are repaid many times over by the results obtained.

Early Stages of Pregnancy.

The diagnosis of pregnancy is usually possible from the end of the second month. In the history, points of value are amenorrhœa, a history of morning sickness, and pain and tenderness of the breasts. On examination at from eight to ten weeks the breasts rarely show anything of diagnostic value. On abdominal palpation one is usually conscious of some resistance above the symphysis pubis. Vaginal examination shows that there is some softening of the cervix, and that the body of the uterus is enlarged, softened, and rounded. I do not lay much stress on Hegar's sign, which can only be obtained if the abdominal wall is very lax. The increased width of the uterus is a useful aid to diagnosis, particularly as it can be estimated by the vaginal fingers alone where, for one reason or another, bimanual examination is difficult. Thus it is particularly useful in cases of retroflexion. The fornices should be palpated for any abnormality.

Patients rarely pay a visit at this stage of pregnancy, except for confirmation of its existence or for a diagnosis, where the history is unusual. Yet a visit at this time is important ante-natally, for many miscarriages result from retroflexion of the uterus, and at this stage a mobile retroflexion can readily be put right, either by postural exercises or, in severer cases, by the use of a watch-spring pessary.

Twentieth to Twenty-second Weeks.

A stage at which many patients pay a first visit is about the twentieth to the twenty-second week of pregnancy. To the history of amenorrhœa are now added the facts of "quickening" and swelling of the lower abdomen. As regards "quickening," it is usually stated that it occurs between the eighteenth and twentieth weeks of pregnancy, but many patients say that they are conscious of fœtal movement considerably earlier than this. On the other hand, movements of flatus in the intestine can be mistaken for fœtal movement ; patients who have already had several children come for confirmation of the presence of pregnancy, complaining of fœtal movement, when they are not pregnant at all.

On examination at 20 to 22 weeks the breast signs are of great importance in primigravidæ. Occasionally they are not conspicuous. The linea nigra shows in the lower abdomen and a definite median swelling is seen and felt there. External ballottement shows the presence of fœtal parts, and the fœtal heart is sometimes heard with surprising distinctness. Even if the fœtal heart is not heard, fœtal movements can frequently be heard as well as other signs of activity, such as the uterine souffle. At this stage vaginal examination confirms the diagnosis, but is not always necessary for this purpose. There is early congestion of the vaginal mucosa, softening is marked, and the swelling in the abdomen can be proved bimanually to be the uterus. Internal ballottement can be produced in the anterior fornix.

---

* A paper read at a meeting of the London Association of the Medical Women's Federation.

Pelvimetry.

Varying with the circumstances of the case, I always consider the size and shape of the pelvis at this, or at an earlier visit, as a guide for the future of the case. It is important to note the stature of the patient. When she lies on her back on the couch, one considers her general outline. A useful "grip" is made by resting the ball of either thumb on the anterior superior spine of the pelvic crest, and clasping the crest in one's hands (Fig. 1). This gives information as to the general size and symmetry of the pelvis; it shows whether the intercristal measurement is greater than the interspinous, and indicates the antero-posterior measurement of the pelvis. One then takes the ordinary measurements, the interspinous, intercristal, and external conjugate.

Internally, I examine the capacity of the pelvis with the patient in Sims's position, judging the width of the pubic arch, sweeping round either side of the pelvis for any abnormality and reaching up towards the promontory. It is difficult to be sure of the promontory unless one can reach slightly beyond it to the beginning of the lumbar curve, and this is only possible when there is contraction of the diagonal conjugate. The resistance of the perineum may play an important part in preventing one from reaching the promontory. Pelvimetry, especially in its wide sense of judgment of the size and shape of the pelvis, is of great importance to the examiner as a guide, but except in extreme cases the crux of the case comes later in the judgment as to whether the particular head in question will pass through the pelvis or not.

First and Second Pelvic Grips.

At 34 to 36 weeks complete ante-natal diagnosis is possible, and I propose going rather fully into the description of a method by which I find students and nurses soon learn to build up a sound diagnosis for themselves.

With the patient's date in mind, first note the general size, shape, and prominence of the abdomen, and also the height of the fundus uteri. The first pelvic (Pawlik's) grip is then made. For this the patient lies extended, breathing freely, and the examiner faces her. The hand is laid above the symphysis, taking the widest possible grip, and as the patient expires each time it is sunk a little deeper into the abdomen (Fig. 2). In favourable cases the hand now finds itself gripping the fœtal head, and it can be determined right away whether this is movable or fixed in the pelvis, and, by manipulating the hand slightly, whether flexion is present. Thus, by this grip alone a complete diagnosis of the lie of the fœtus may be made, and the remaining grips are only confirmatory. If the head is not felt by this grip and the succeeding one, it must be sought elsewhere before an attempt is made to discover other parts of the fœtus.

The second pelvic grip is now taken, facing the patient's feet, with her thighs and knees slightly flexed to relax the abdominal muscles. Again, a wide grip is taken, capable of enclosing the whole head, and the finger tips are sunk downwards and backwards, again with each expiration, until the presenting part is felt between the hands (Fig. 3). This grip is perhaps even more useful than the first, and in most cases confirms it. A head that appeared fixed sometimes shows itself somewhat movable, when the muscular tension is relieved, and occasionally the flexion of the head is found to be towards the opposite side from that expected. This is because the Pawlik grip does not always admit of the palpation of that part of the head which lies posteriorly.

Fundal Grip, &c.

The fundal grip is now practised and is of particular importance when the head has not been found at the pelvic brim, when there is uncertainty as to whether the presenting part is the head or not, or when multiple pregnancy is suspected. It is most important to find the head before proceeding further with the diagnosis. If the head is at the fundus its main bulk rests to one side or other of the middle line and two grips are taken accordingly, the hands being placed sufficiently widely apart to allow of the enclosure of the whole head (Fig. 4). I impress the importance of width of grip because I find that beginners rarely make it wide enough. The deciding points about the head are its firmness and roundness, the fact that it ballottes between the examining hands, and that it is divided from the rest of the body by a definite gap. Ballottement of the head at the fundus can also be obtained by laying one hand over the prominence produced by it and shaking it within the convexity of the hand. The breech never moves sufficiently to give this result.

To decide where the fœtal back lies, a useful grip is one by which the resistance of the two sides of the lower abdomen is compared. The fingers of one hand are spread between the anterior superior spine and the umbilicus and sunk deeply into the abdomen (Fig. 5). The same hand is used in exactly the same way on the other side. This shows at once whether the back is anterior or not, and by the definite resistance of one side on which side it is. Confirmation is obtained by holding the uterus in position with one hand while palpating with the other, and vice versa. The fœtal heart is now sought according to the diagnosis made and used as a confirmatory sign of diagnosis.

Engagement of the Head in the Pelvis.

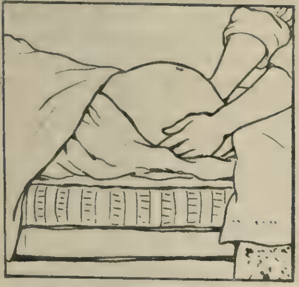
It used to be taught that in primigravidæ the head did not begin to engage until the thirty-sixth week of pregnancy, and then gradually sank down into the pelvis, and that in multigravidæ engagement did not occur until labour began or shortly before this. We must consider what produces engagement of the head and what determines a difference between primi- and multigravidæ.

As pregnancy advances stretching of the uterine and abdominal walls increases, and, given a normal pelvis and fœtal head, the tension produced thereby overcomes the resistance offered by the pelvis and the structures in it, and the presenting part engages in the pelvis. The tension is greater in primigravidæ because neither the uterus nor the abdominal wall has been stretched before; hence the fœtal head usually engages early, but in multigravidæ with well-preserved musculature engagement occurs also. Usually engagement has begun at 34 weeks. Occasionally we find a head quite deep in the pelvis at 28 to 30 weeks. If the head has not engaged, or does not show signs of engaging, by 36 weeks in a primigravida the reason must be carefully sought. If the pelvis is small or asymmetrical the fact is already known. The head may be large or in a bad position; a loaded rectum will push the head out of the pelvis, and a low-lying placenta acts in the same way. The grip I now use to the exclusion of others to determine whether a head is likely to go through a given pelvis or not, is one by which I press down the fœtus towards the pelvic brim from the fundus, when the abdomen is lax, and lay the other hand flat just above the symphysis (Fig. 6). Having made a careful diagnosis of the presentation and position of the head previously, I then judge by the amount of overlapping present.

Maturity of the Fœtus.

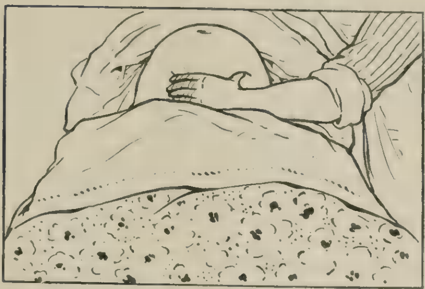
It is important to be able to give a sound opinion on the maturity of the fœtus for two reasons: first to be able to give advice to those who require it, as for instance, to a mother who has conceived during the amenorrhœa of lactation; and, secondly, to determine whether the patient's dates are reliable. The question of maturity can be decided only as a judgment on the average find, since normal full-term infants vary so considerably in size, and such signs as deep engagement the head may be altogether misleading. First note e height of the fundus uteri and the general size of e abdominal swelling; then, if the fœtus is suffi- ently mature, note the size of the head and its sition as regards the pelvis—whether floating above e brim, engaging at the brim, or deep in the pelvis. Until the uterus reaches the umbilical level at about weeks the height of the fundus is a fairly good uide; after this all the points above must be taken to consideration together. I rely most on the size the fœtal head, and, gripping this with one hand d the breech with the other, consider the size of the ild. It is well in multigravidæ to find out the weight former children at birth.

FIG. 1.



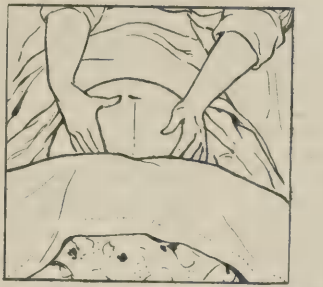
Ball of either thumb on anterior superior spine of pelvic crest, the crests being clasped in the hands.

FIG. 2.



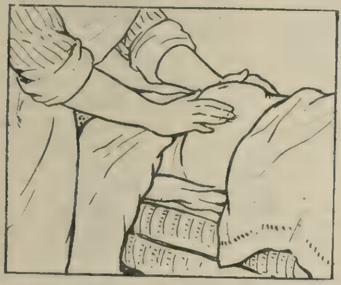
First pelvic (Pawlik's) grip; hand above symphysis pubis, as widely extended as possible, to grip the fœtal head.

FIG. 3.



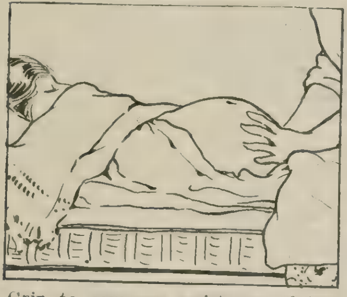
Second pelvic grip. The position of the hands indicates flexion of the head towards the right side.

FIG. 4.



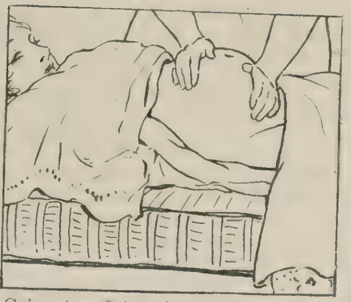
Fundal grip; width of grip is important.

FIG. 5.



Grip to compare resistance of two sides of lower abdomen.

FIG. 6.



Grip to determine likelihood of passage of fœtal head through pelvis.

When testing the size of the abdominal swelling d that of the fœtus as compared with the patient's es, one's attention is drawn to a number of abnor- lities, and to the question of multiple pregnancy. for instance, we find an abdomen abnormally large the date, with a head of medium or small propor- ns, it often pays to search for a second head.

Presentation and Position of the Fœtus.

n the early stages of pregnancy the position is stable. At 28 to 30 weeks breech presentations are mon. Spontaneous version is still liable to occur ween 32 and 34 weeks, but after this it is rare. It nteresting to note how often there is change of ition in vertex presentations late in pregnancy en the fœtus appears to have settled down to its l position. I have noticed this often, and recently mined a patient at weekly intervals four times ning, shortly before delivery, and found L.O.A. l R.O.A. alternatively. The fœtus also quite often es up positions that do not come into the usual ssification.

Vith regard to the turning of breech presentations, o not attempt external version until about the ty-fourth week, since there is still likelihood of its urring spontaneously. If left later than this date re is often difficulty in performing version on ount of the size of the child—the head gets under costal margin, the breech is engaged in the pelvis, it is difficult to obtain a grip upon it. In performing version, if the breech is engaged, the patient must rest in the Trendelenburg position until it is disengaged. The head is taken in one hand, the breech in the other, and it is just as important to push the breech up as to draw the head down. No actual force should be used and the manipulation ought not to hurt the patient. If version does not occur with comparative ease, I allow the presentation to persist in normal multigravidæ and in primigravidæ with well-shaped and good-sized pelves. Death of the fœtus or accidental hæmorrhage may occur after version, and the risk of breech delivery in these cases is not great. In primigravidæ with small or even medium-sized pelves version should be performed under an anæsthetic if necessary. An extended breech will rarely turn, since the legs act as splints preventing flexion of the body.

The Fœtal Heart.

In listening for the fœtal heart, it is always wise to take the patient's pulse also. Rapidity of her heart action may be produced through nervousness, and confusion between the two is possible. A monaural stethoscope with a wide base for collecting sound is the most satisfactory instrument for all-round use. Until about the twenty-second week the fœtal heart is often inaudible. Occasionally it is surprisingly distinct, depending largely on the nearness of the fœtal back to the abdominal wall. Until 26 to 28 weeks, when the position of the child begins to stabilise, it is best to listen for the heart over the uterus in the middle line and, if it is not heard there, over some solid part of the fœtus determined by palpation. After the child has adopted a stable position, in all presentations when the back is anterior, the heart is heard best over that part of the back nearest to the heart. It is according to this known position, determined already by palpation, that it should be sought and its intensity compared with that in other positions in cases of doubtful diagnosis. In a vertex presentation with engaged head, the point of maximum intensity is roughly on a line drawn from the umbilicus to the anterior superior spine of the pelvic crest; if the head floats freely above the pelvis it is higher than this. In breech presentations the point of maximum intensity is rarely above the umbilicus—the head is above the umbilical level, the back below it. Only in those cases where the child's head is under the costal margin—i.e., towards full term with a large child—does one hear it best at the umbilical level or above it. In posterior positions the heart sounds are conducted indirectly, and may not be best heard at the point nearest the heart.

DIAPLYTE TUBERCULIN.

BY CLIVE RIVIERE, M.D., F.R.C.P. LOND.,
PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS.

THE arrival among us of a new tuberculin—for Dreyer's antigen is no less than this, though we may hope it will prove more—again brings into prominence the important subject of dosage and administration of these substances, powerful for harm as well as good, and necessarily given at the start in doses almost immeasurably small. Tuberculin, especially in the treatment of pulmonary tuberculosis, has fallen into practical disuse in this country during the past ten years, and I find but few of the younger physicians among us have had experience of its administration. Our pathologists, moreover, though well versed in the small infrequent dosage suitable to the treatment of localised tuberculosis, have for the most part ignored the method of frequent and rising dosage accepted all the world over as applicable to the treatment of pulmonary and other forms of autotoxic tuberculosis. Under these circumstances I am tempted to restate some of the essentials of safe administration under the latter method, especially with a view to the avoidance of unexpected large reactions which may vitiate the success of the method and imperil the recovery of the patient. I shall speak only of dosage and of method of administration.

Preparation of Antigen.

The preparation of the antigen for injection demands (1) a diluent, in this case sterilised normal saline containing 0·15 per cent. formalin; (2) an accurate tuberculin syringe graduated in 1/10, the barrel for accuracy being about 8 cm. long (syringes of the Record type are the best); (3) a long 10 c.cm. graduated measure or pipette; and (4) some 10 c.cm. stoppered bottles. 1 c.cm. of the "original solution" (in this case Dreyer's antigen) with 9 c.cm. of the diluent now makes dilution 1, whose bottle is so numbered; 1 c.cm. out of this bottle (dil. 1) with 9 c.cm. of diluent now forms dil. 2; and 1 c.cm. of dil. 2 with 9 c.cm. of diluent makes dil. 3, and so on, each dilution being 1/10 strength of the one above. Now it is obvious that 1 c.cm. of dil. 1=0·1 c.cm., 1 c.cm. of dil. 2=0·01 c.cm., and 1 c.cm. of dil. 3=0·001 c.cm. of "original solution," and so on. This is to state the dose in fluid measure, which is now always done for convenience, and also for avoidance of misunderstanding (since Koch often spoke of milligrammes when he meant cubic millimetres, and, moreover, discussion arose as to the solid contents of T.R., which was made from 10 mg. of tubercle bacilli per c.cm., but found to contain whenever completed only 2 mg. of solid substance (Wright; Ruppel)). If it is demanded, for Dreyer's antigen, that a dose be stated in mg. of solid substance, then this is easily arrived at by dividing the dose in c.cm. by 5 (since 1 c.cm. contains 0·2 mg. of antigen). Thus 1 c.cm. of dil. 3 contains 0·001 c.cm. of original solution, or 0·0002 mg. of solid antigen, and 1 division (1/10 c.cm.) of syringe 1/10 of this, or 0·000 02 mg.

Now when we come to the matter of initial dosage we find that Dreyer's antigen is weaker than any of the tuberculins in common use—it may, perhaps, for convenience be considered to be 1/10 strength of T.R., the weakest of the older tuberculins whose initial dose could be safely put at 0·001 c.mm., or 0·000 001 c.cm.—i.e., 1 division (1/10 c.cm.) of dil. 5. With Dreyer's antigen it should be safe, even in febrile cases, to commence with a dose 10 times this strength—i.e., 1 division (1/10 c.cm.) of dil. 4. In afebrile cases a dose of 2½ or 5 divisions (¼ or ½ c.cm.) of dil. 4 should be safe, this latter representing 1/100 000 mg. of the solid antigen.

Dosage.

So much for dose nomenclature, which need, fortunately, no more be bothered with once the initial dose is decided on. After that the dosage runs up in divisions of the 1 c.cm. syringe from one diluent to the next, from dil. 4 to dil. 3, to dil. 2, and so on. It is, in especial, of the method of graduating this rising dosage that I wish most emphatically to speak. It is here that danger to the patient arises, since avoidance of unexpected reactions (I shall say nothing here of reactions deliberately forced!) depends very closely on the smoothness of this upward gradient of dosage. Now it is obvious that if we rise in divisions of the syringe 1, 2, 3, 4, 5, 6, 7, 8, 9, that is in arithmetic progression, that the rise from 1 to 2 is doubling while the rise from 8 to 9 is but an increase of 1/8—the rise 1 to 2 is a "cliff" in dosage at which a "reaction" is likely to occur. Tuberculin administrators have got over this difficulty by making such a sequence as 1, 1·5, 2, 3, 5, 7, 10, 15, &c., but this is, after all, but a rough and ready device which meets the need but partially. It does not really do away with "cliffs," and it condemns us to a rapidity of rise which may not suit the particular case under treatment. We require, not only a smooth rise, but a rise whose steepness we can modify to meet the individual case. The only logical way to achieve these two ends is by the use of a table where doses rise in geometrical progression, always by the same multiple, however small, and where many different gradients are provided to choose from. Such a table was prepared for Lawrason Brown in the past, and a modification of it, made by Egbert Morland for a book on Tuberculin Treatment in which he and I collaborated,[1] is here in part reproduced. In this table the numbers refer to divisions of the 1 c.cm. tuberculin syringe (which must be divided in 1/10). Since no more than 1 c.cm. can be given with this syringe no mistake can be made with these numbers, and the decimal point may be put in or omitted as desired. Having ascended a column of dosage on one dilution, we pass to the next stronger dilution and work up it on the same basis, 1 division (1/10 c.cm.) of the new, stronger dilution being equal to 1 c.cm. of that we are leaving.

10·0	10·0	10·0	10·0	10·0	10·0	10·0	10·0
4·6	5·6	6·3	6·8	7·5	7·9	8·3	8·6
2·2	3·2	4·0	4·6	5·6	6·3	6·8	7·4
	1·8	2·5	3·2	4·2	5·0	5·6	6·5
		1·6	2·2	3·2	4·0	4·6	5·4
			1·5	2·4	3·2	3·8	4·65
				1·8	2·5	3·2	4·0
				1·3	2·0	2·65	3·4
					1·6	2·2	2·9
					1·3	1·8	2·5
						1·5	2·15
						1·2	1·85
							1·6
							1·4
							1·2
1·0	1·0	1·0	1·0	1·0	1·0	1·0	1·0
3	4	5	6	8	10	12	15

With such a table the initial dose, generally much below the patient's reaction point, may be rapidly pushed up, on a basis of 3 or 4 doses to each dilution or by doubling (a convenient plan), till it begins to be ffective, and thereafter a basis of, say, 10 or 12 doses) each dilution (see Table [10] and [12]) may be sed to continue the treatment. In recording the osage it is convenient to put the "dilution" as a umber in a circle, and the "basis" of dosage—i.e., s gradient—as a number in a square. Thus at a lance the whole dosage and method are made apparent. or instance, starting with 2·5 divisions of the yringe in dil. 4, the doses might read as follows: 4) 2·5, (4) 5, (4) 10 (or (3) 1 which is the same), 3) 2, (3) 4. At this point, up to which we have oubled, let us suppose evidence of "reaction," that , that the dose has now become "effective." Now e need to get on to a slower "basis," let us say 10], and we continue (3) 5, (3) 6·3, (3) 7·9, (3) 10, 2) 1·3, (2) 1·6, &c.

---

[1] Tuberculin Treatment. London: Oxford Medical Publications. Second edition. 1913.

Of the means whereby control of dosage is attained, nat is reactions and "subreactions," I shall not peak here, except to remark that it seems likely local reactions" will play small part in control of losage by Dreyer's antigen, and that hence we nust be all the more watchful for slight effects on emperature (both down and up) and on general ymptoms, as indications that the "threshold of esponse" is reached, and a more sloping gradient f dosage indicated.

If much of the foregoing seems elementary and bvious may I plead first the supreme importance to ır patients that it should be understood by all; econdly, the extraordinary ease with which mistakes in tuberculin dosage may be, and have been, nade; and, thirdly, the importance that any "new a" should escape disaster at the outset. If this ommunication is the means of spreading the use of geometrical dosage" I feel that it will have served useful purpose.

HREE CASES OF BILATERAL RENAL CALCULUS.

BY CHARLES NOON, F.R.C.S. ENG.,
ASSISTANT SURGEON, NORFOLK AND NORWICH HOSPITAL.

THE following cases illustrate some important oints in the diagnosis and treatment of bilateral nal calculi.

CASE 1.—Female, aged 31, was admitted to the Norfolk nd Norwich Hospital on August 9th, 1921, complaining of ain in right side of abdomen.

History.—The patient stated that during the last six years e had suffered with occasional attacks of pain in the right de of the abdomen, the pain radiating into the right loin. ne attacks of pain varied in severity, but on five or six casions she was confined to bed for about a week. The vere attacks were followed by the passage of small stones ith the urine; and on five or six occasions she had passed least 12 stones during each attack. She had never, so far she knew, passed any blood in the urine. On August 5th, eling quite well, she went to the seaside; on the 6th she as seized with a very severe pain in the right side of the domen. The urine was thick and she passed it frequently th severe pain. On the 7th she returned home and was lmitted to hospital on the 9th.

Condition on Admission.—The patient is a pale, ill-urished weakly-looking woman. Temperature 100° F., lse 98, respirations 24. Eyes: pupils equal reaction to ht and accommodation; tongue furred. Chest: thin, oves well and equally; lungs normal. Heart: apex beat th space inside nipple line; sounds normal. Abdomen: not stended; abdominal wall thin and lax. A swelling, seen scending below the right costal margin, moved on respiration. The swelling was easily palpated; it had well-defined argins, did not cross the middle line, was easily pushed ck into the loin; its manipulation caused much pain. ne swelling was resonant. Several hard bodies like renal lculi could be felt; on manipulation a sensation of crepitus as also felt. Left kidney not palpable or painful.

Urine, specific gravity 1012, alkaline, no blood or casts; bumin, a trace. There was a sediment on standing and e urine contained a large quantity of pus. Re-examination: lvis of right kidney contained many calculi. There were o stones in the left kidney.

The patient, after a week's treatment, considerably proved; the temperature fell to normal, and the amount pus in the urine considerably decreased.

Operation.—Right pyelo-lithotomy and removal of 23 calculi on August 15th. Under chloroform and ether the kidney was exposed by a right lumbar incision, 5 inches in length, separated from the surrounding perinephric tissue, and delivered through the incision without difficulty. The pelvis of the kidney was much dilated; it was incised and three large and 20 small calculi were removed. They were faceted and irregular in shape, the three large ones having a deposit of phosphates upon them. The total weight of the 23 was [illegible] oz. A considerable part of the kidney tissue had been destroyed, but a fair amount of secreting tissue remained. A catheter was passed through the pelvis of the kidney and so into the ureter and bladder. There was no obstruction, the catheter was removed, and the incision in the pelvis closed. The lumbar incision was closed, with drainage. The patient made a good recovery. The lumbar wound healed in four weeks, and the patient was sent to a convalescent home.

Second Admission to Hospital.—The patient was again admitted on Dec. 3rd, 1921. Her general condition had much improved; she had increased in weight and had no pain since her discharge from hospital. On examination, the right kidney was only just palpable; no pain in right loin. Urine: Specific gravity 1010, acid; albumin, a trace; small amount of pus still present. X ray examination: no stone now present in right kidney; two stones in left kidney.

Operation.—On the 6th, left lumbar nephrolithotomy, two stones were removed; they were similar in substance to those removed from the right kidney, and weighed ½ oz. together. The wound was closed with drainage, and the patient made a good recovery from the operation, the wound being quite healed three weeks after the operation.

CASE 2.—Male, aged 36, admitted to the Norfolk and Norwich Hospital on August 7th, 1921, complaining of dull aching pain in both loins.

History.—Patient stated that in 1914 he began to notice dull aching pain in both loins. In October of that year he was admitted to a Naval Hospital after passing a small quantity of blood in the urine. He was X rayed, and calculi were found in both kidneys. He was discharged from the Service without operation. During the past five years he had suffered with occasional attacks of pain in the loins. The attacks of pain had got more frequent of late and he had never felt quite well.

Condition on Admission.—The patient was a healthy-looking, well-developed man. Temperature 98° F., pulse 80, respirations 18. Eyes reacted to light and accommodation, Cranial nerves normal, tongue clean, tonsils not enlarged, no palpable lympathic glands in neck. Chest: heart and lungs normal. Abdomen: abdominal wall muscular and well developed, moved well and equally on respiration, abdomen not distended. There is tenderness on palpation over both kidneys, especially the left, the lower pole of which is palpable. The liver is not enlarged, no tenderness over the appendix. Upper and lower extremities normal. Urine: quantity, two pints in 24 hours; reaction acid; specific gravity, 1014; albumin, a trace. No blood. A few pus cells present on microscopic examination. X ray examination: A large stone in pelvis of right kidney, a small stone in pelvis of left kidney. Cystoscopic examination: urine could be seen coming from the right ureteral orifice, but none from the left. It was concluded that the upper end of the left ureter was blocked by a stone. Operation advised.

Operation.—On August 22nd a left pyelo-lithotomy. Left kidney exposed through a left lumbar incision, separated from the surrounding tissues and drawn out of the wound; a calculus could be felt in the pelvis of the kidney and upper part of the ureter. The kidney was turned forwards and upwards so as to expose the posterior aspect of the pelvis. An incision was made into the posterior aspect and a stone extracted without difficulty. The ureter was then explored by passing a catheter from its exposed upper end into the bladder. There was no obstruction. The incision in the pelvis was then sutured, and the kidney returned into its bed. The lumbar wound was closed with drainage. The wound healed in the course of three weeks and there was no discharge of urine from the loin. The patient was discharged from hospital a month after operation.

Second Admission to Hospital.—The patient was again admitted in October, 1921; on Oct. 30th, the right kidney was explored and two large stones were removed from the pelvis and cortex of kidney. The ureter was examined and no obstruction was found; the wound was closed with drainage and the patient made a good recovery. The stones consisted of phosphates. Two branched, faceted stones were removed from the right kidney, together weighing 1¼ oz. One beak-shaped stone removed from the left kidney and ureter, weight ¼ oz.

CASE 3.—A male, aged 46, a sailor, was admitted to hospital on Oct. 10th, 1918, complaining of pain in left loin and occasional passage of blood with the urine.

History.—The patient stated that in 1902 a stone was removed from the left kidney. He remained in good health until about 1917, when he began to suffer with attacks of pain in the left loin, the pain being referred to the groin. After a severe attack of pain he would occasionally pass a little blood in the urine. He served in the Navy from 1914 until October, 1918, when he was admitted to hospital.

Condition on Admission.—A fairly healthy-looking man. Temperature 98° F., pulse 88, respirations 20. Cranial nerve normal, tongue clean, heart and lungs normal. Abdomen: moved well and equally on respiration, no distension, tenderness on palpation over both loins, but the kidneys could not be felt; liver not enlarged; a scar in the left loin, the result of a previous operation. Urine: specific gravity 1016, acid; no albumin, no sugar, On microscopic examination a few red blood cells present. X ray examination: A stone in each kidney.

Operations.—On Nov. 14th left lumbar pyelo-lithotomy was performed and a large, single, flattened stone removed from the pelvis of left kidney. The pelvis was sutured and the wound closed with drainage. There was no escape of urine through the loin, and the wound healed by primary union. On Jan. 9th a similar operation was performed on the right side and a single stone was removed from the pelvis of the right kidney. The patient made an excellent recovery from the operation. An X ray examination was made after the operation and no sign of stones was to be seen; but stones recurred in both kidneys and the latter were again explored in 1920, stones being removed from the pelvis of each kidney. The patient made a good recovery after each operation.

Remarks.

Sir John Bland-Sutton in his recent selected essays remarks, "The fate of patients who have stones removed from one or both kidneys is an important matter, and one on which little has been written." Among points for consideration in cases of bilateral renal calculi perhaps the most important are: (1) Do the symptoms and physical signs indicate operative treatment? (2) If operative treatment is indicated shall both kidneys be operated upon at the same time or shall one be operated upon before the other? (3) By what method shall the calculi be removed from the kidney? Operative treatment must not be considered necessary simply because X ray investigation shows calculi in the kidneys; the position of the calculi, their size and shape, the symptoms and physical signs to which they give rise, should all be taken into consideration. The three cases described illustrate some interesting features of the disease. Renal calculus may be one of the most chronic surgical diseases, but complications such as renal colic, infection of the urinary tract, and calculous anuria—the gravest and most fatal of all urinary calamities—may occur at any time and almost without warning. Although the ordinary text-books on surgery do not seem to urge operations on cases of bilateral renal calculi, it would seem well to perform it as early as possible in suitable cases where complications seem likely to occur to prevent excessive damage to the kidney taking place from the pressure of the stone, and to prevent the possibility of calculous anuria. The operation, if done at the proper time and in the proper way to avoid complication, and not because of their development, should have a very low mortality.

When operative treatment is indicated, most surgeons consider it best to operate on one kidney at a time, allowing a reasonable interval to elapse before the other operation, but some have advocated operating on both kidneys at the same time; if, however, the only reason for operating on both kidneys at one time is the desire to avoid a second operation, it does not seem to me to be sufficient. When the kidney has been exposed, the importance of determining the correct procedure for the investigation of the kidney and for the relief of the condition present cannot be over-estimated. Sometimes it is not easy to locate the stone; in such a case it is always wise only to do nephrolithotomy or splitting of the kidney as a last resort. This procedure is rarely necessary. Nearly all stones can be located and removed by the performance of pyelotomy and pyelolithotomy combined with the operation that may be described as restricted nephrolithotomy—that is, the making of a small incision through the cortex of the kidney and removing a stone through this small incision. In some complicated cases it may be necessary to remove the kidney.

The length of time during which patients may suffer from renal calculus is noteworthy; in these three cases the condition had in every case been present for more than five years, and in one case over 20 years. In this, as in other surgical diseases, it is often the complications that bring the patient under observation. The disease itself may be present for a considerable time without causing any symptoms.

In bilateral renal calculus it would seem that it is common for the patient to refer the symptoms to the side only, and it would often be impossible to make a diagnosis without the assistance of the X ray. Each case illustrates the importance of X raying the entire urinary tract when a stone has been found in any part of it. It has been recorded that the first successful skiagram of renal calculus was taken by J. McIntyre, of Glasgow, in 1896. When it is realised that 50 per cent. of the patients sent to the radiographer with the diagnosis ? renal calculus are returned as negative, it at once becomes apparent what an important factor the X ray has in the diagnosis. It is almost impossible to diagnose bilateral stone without the aid of X ray. The cystoscope is of additional use in deciding on which kidney to operate, and gives definite information as to the obstruction to the ureter. It is uncommon to be able to palpate renal stones, but in one of the cases recorded this could be done without any difficulty. Similar cases have been recorded by Pick and Morris.

Bilateral renal calculi are not uncommon, but not many records of the treatment of such cases are to be found in the literature. Kummel, in 101 consecutive cases of renal calculi, found both kidneys involved in 16 cases. Bevan states that the proportion of bilateral cases numbers about 20 per cent. Küster, in 764 cases of stone, found 90 bilateral; he collected 20 cases in which double operations were performed, and found ten successful cases, three recovered with fistula, and seven died, the deaths being due in most cases to uræmia. Simpson, of Liverpool, has recorded an interesting case of bilateral nephrolithotomy for multiple calculi in a boy aged 8; in his paper he mentions some details of the history of the operation for removal of stones from the kidney. He records that the operation is said to have been performed in the time of Hippocrates, but not again for many centuries after that time. In 1579 it is recorded that Paré operated upon an archer reprieved from death, but it is not stated that the stone was removed.

In 1696 Marchette, of Padua, is said to have extracted a stone from the right kidney of the English consul at Vienna, and in 1773 Paul, of Stroud, is believed to have removed a stone from the back of a woman and effected a cure. The discovery of anæsthetic and antiseptic soon made the removal of stones from the kidney an operation which might be undertaken with some hope of success. In 1869 Thomas Smith described the operation and Dawson, of Ohio, tried it in 1872, but the patient died. At St. Bartholomew's Hospital Callender, in 1873, and Morrant Baker, in 1874, attempted the operation, but both patients died. In 1876 Savory, guided by a sinus, tried it again and cured his patient. In 1878 Teale operated upon an unsuccessful case, and in 1880 Morris successfully recovered a stone from the kidney. From that time onwards the operations on the kidney have been numerous and successful.

DUODENAL DIVERTICULA.

WITH REPORT OF A CASE OF GANGRENOUS DIVERTICULITIS.

BY G. P. B. HUDDY, M.S. LOND.,
F.R.C.S. ENG.,
SURGICAL REGISTRAR, LONDON HOSPITAL.

HISTORICALLY our knowledge of duodenal diver- cula can be divided into three stages. (*a*) A long eriod of just over 200 years from 1710 to 1912; uring this period these pouches were recognised as eing occasionally present, and gradually their acroscopic and microscopic appearances were escribed. (*b*) A short period from 1912 to 1922; in hese ten years it was shown that the condition could ometimes be discovered in the living subject by means of the X rays. (*c*) The third stage—that of the escription of pathological conditions of these pouches nd the resulting symptoms; this has largely followed n and depended upon the work of the radiologist.

In 1710 Chomel[1] discovered post mortem in the ody of a female, aged 80, who had died of apoplexy, pouch connected with the duodenum, which con- ained 22 stones of a yellow-white colour, with olished surfaces and solid but not stony hard con- stency. He then described the symptoms from which he suffered: "La dame qui portoit ces pierres ne omissoit point; mais deux heures après qu'elle avoit mangé elle sentoit une legere douleur vers l'endroit ù le sac étoit placé. C'étoit-la justement le temps où chile de la nouvelle digestion couloit dans le uodénum, qui ne lui donnoit pas un passage assés bre, parcequ'il étoit comprimé et gesné par le sac." rom this description it is doubtful whether the ouch would correspond with an ordinary duodenal iverticulum.

In 1761 followed Morgagni's[2] description, "in the ody of an apoplectic man—a diverticulum connected ith the duodenum about 2 inches below the pylorus, hich was a kind of cellule not very protuberating, but ig enough to admit a finger, with no trace of present r past ulceration." The first description in this ountry was by Habershon[3] in 1857, who said, diverticula have been noticed but are exceedingly are as compared with those arising from the lower art of the ileum; these pouches in the duodenum onsist generally of mucous membrane and might be onsidered as a form of hernial protrusion of that embrane." From this time onwards pouches were escribed by various authors, and in 1893 Perry and haw[4] discussed 14 cases, dividing the pouches into two ypes—(i.) those in which the surrounding intestine as apparently normal, and (ii.) those in which the ouch was the result of ulceration or traction. They so discussed the age incidence, sex, site, and the ct that the pouches are occasionally multiple. eith also in 1903 and 1910[13] increased our knowledge this subject. The result of these various descrip- ons was that in 1911 Buschi of Bologna[5] was able to ummarise 54 cases.

In 1912 Bauer[6] mentioned a case in which a pouch as thought to have caused pyloric obstruction; perative treatment (gastro-jejunostomy) was carried ut, but the patient died on the eleventh day. The rst pouch said to have been removed surgically was ported in 1914 by Forssell and Key, quoted by ase,[17] in a female of 41; the condition was discovered y means of X rays and removal yielded a cure of ersistent digestive complaints. In 1917 Ritchie and cWhorter[7] found 76 cases in the literature with 97 verticula, together with 11 cases with 12 diverticula ublished by radiologists. The radiological aspect as developed largely by Cole, Case,[17] and in this ountry by Spriggs.[8]

Causation.

There has been much discussion as to the manner in hich these pouches are produced, and various heories have been advanced. The following ætio- gical factors have to be considered: (1) Whether these diverticula are congenital or acquired; (2) if acquired, whether of the traction or pressure type.

- Diverticula
  - Congenital (true)*
  - Acquired (usually false)
    - Traction
    - Pressure
      - Weakness of wall.
      - Pressure within.

* i.e., composed of all layers of the bowel wall.

It will be seen from the following that these duodenal diverticula are of various types, into whose formation the above factors enter.

Congenital Diverticula.

Many observers regard duodenal diverticula as being of congenital origin, and have advanced the following points to support this theory:—

(1) The duodenum gives off the pancreatic and biliary buds and so is regarded as being a likely site from which, owing to excessive activity, other similar buds might be extruded; but it is to be noted that diverticula are also common in the colon, especially the lower colon, where there are no such organs as the liver and pancreas developed, whereas in the region of the cæcum and ascending colon, where there is a bud (the appendix), these diverticula are rare.

(2) The presence of portions of pancreatic tissue in the wall. This, however, could be accounted for otherwise, as the presence of such islands of pancreas in the muscular wall of the duodenum would leave a weak area from which during life a pouch might be developed.

(3) The absence in the majority of cases of any pathological condition—e.g., ulcers, adhesions, &c. This is certainly the case, but a pathological condition is by no means essential to the production of a pressure pouch.

(4) A case of Shaw's[9] in which, in association with atresia of the duodenum, there was a congenital sac. This shows the undoubted possibility of these pouches being congenital in origin, but here there was atresia of the duodenum, and so the condition was far from representative; moreover, the pouch was shallow and arose from the first part of the duodenum, a rare position.

(5) Buschi[5] observes that on account of the fluid nature of the duodenal contents the stasis would have to be of a high grade to produce pouches. It would seem, however, that the pressure exerted by fluid, even if slight, might start a pouch at some weak site, and once formed the condition would be progressive.

(6) In Ritchie and McWhorter's case[7] the history goes back to childhood and so suggests a congenital origin. This does not appear to be a very forcible argument, as a history of digestive disturbance cannot be definitely assigned to the presence of such a pouch.

(7) The presence of associated abnormalities—e.g., œsophageal pouches, bladder pouches, &c.

(8) Lewis and Thyng[10] showed the presence of intestinal diverticula in embryos of the pig, rabbit, and man.

(9) The fact that the diverticulum may be composed of all layers of the normal duodenum. This is, however, uncommon—an example is afforded by a case recorded by Murchison[11] and the case is reported below.

The conclusion may then be drawn that congenital pouches may occur, but they probably only form a small percentage of duodenal diverticula. Evidence in favour of an acquired origin of these pouches is as follows:—

(*a*) Anatomically, the pouches usually arise from weak areas of the wall—e.g., the retro-peritoneal aspect, and where the musculature is weakened by the passage of the pancreatic and biliary ducts or by blood vessels. In a case reported by Dorrance[12] the opening was situated 3·5 cm. below the papilla, but in this case there was a large artery and vein situated in the wall.

(*b*) Histologically, as will be shown below, in the majority of cases reported the structure of the wall was that of a false diverticulum—i.e., not composed of all layers of the duodenal wall.

(*c*) Clinically and radiologically, these pouches have usually been discovered in old subjects, and very rarely described in the young.

(*d*) Experimentally, it has been found that if produced artificially the rupture occurred regularly in the retro-peritoneal aspect. Too much weight cannot, however, be attributed to this, as other workers have failed to confirm this observation.

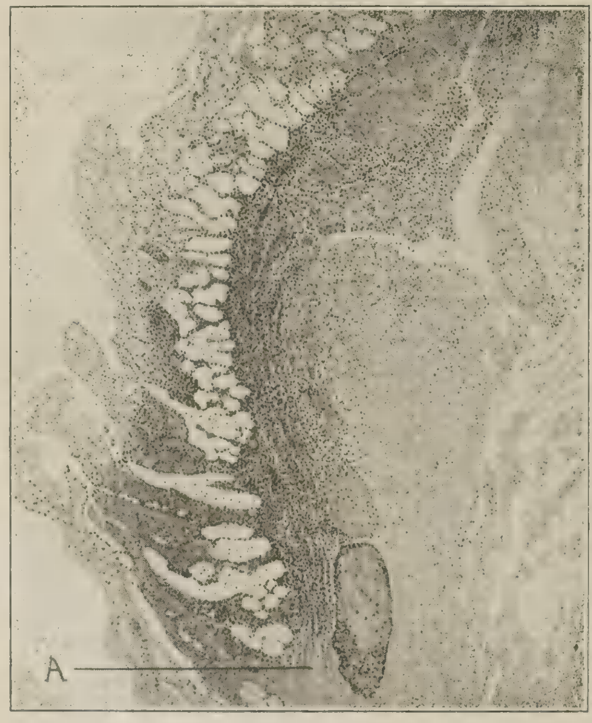
(*e*) By analogy, colonic diverticula arise at the site of penetration of the muscular coat by blood vessels.

(*f*) Some are definitely of an acquired origin and due to traction, but these form a small proportion. The traction may be due to adhesions from gall-bladder disease, or, some authors say, to an atrophic pancreatitis; more probably, however, in this latter case the pancreatitis is secondary to the presence of the diverticulum. It is improbable that the pancreas causes traction pouches, because (1) there are many cases of pancreatitis without diverticula, (2) the pouches are usually easily separated from the pancreas. Keith[13] says traction pouches may be produced in association with visceroptosis, by a prolapsed condition of the duodenum resulting in dragging by the common bile duct.

In the London Hospital in March, 1922, a case under the care of, and operated upon by, Mr. A. J. Walton afforded rather an unusual example of a traction pouch, occurring, however, in the first part of the duodenum.

A married woman, aged 38, admitted on March 6th, 1922. The pre-operative diagnosis was lesser curve ulcer—pyloric obstruction, visceroptosis. On the 7th a barium meal examination was made by Dr. M. H. Jupe, who reported "Bilocular stomach with penetrating ulcer of the lesser curve; gastroptosis and a peculiar condition of the duodenum, so that it appeared to pass transversely to the left to the region of the ulcer." Operation was performed on the 8th: partial gastrectomy, removal of first stage duodenum, appendicectomy. There was an ulcer of the lesser curve adherent to the pancreas and with hour-glass constriction of the stomach; in the duodenum there was a pouch, [illegible] in. × 1½ in., adherent to the lesser curve ulcer.

Fig. 1.—*Section of Apex of Inflamed True Diverticulum of Duodenum (case reported below).*



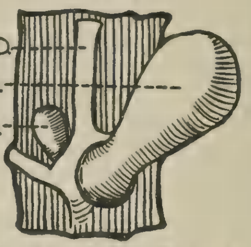
Shows partly necrosed mucosa and submucosa. That the diverticulum is true is shown by the presence of remnants of the muscular coat close to Brunner's glands at the point marked A. The muscularis mucosæ, which should lie superficial to Brunner's glands, cannot be recognised. There is great congestion of vessels and hæmorrhage with acute inflammatory infiltration.

Description of Pouches.

Duodenal pouches may arise from any of the three portions into which the duodenum is anatomically divided. The great majority are found in the second portion of this segment of the intestine and particularly on the postero-internal aspect, in close relation to the ampulla of Vater, so that diverticula at this particular site have been termed by the French "diverticules périvatériens" (Letulle). Spriggs[8] analysed the position of the neck of the sac in 57 cases and obtained the following figures: First part, 11; second part, 41; third part, 3; first and second parts, 2. This, however, probably gives rather a high proportion for those situated in the first part, as he quotes his own ten cases, none of which were in the first part; also Ritchie and McWhorter[7] in their 97 diverticula found only eight in the first stage.

From its duodenal origin the pouch may extend in any direction, but by far the most common is inwards towards the concavity of the duodenum, where it comes into close relationship with the pancreas, from which, however, as a rule it separates readily. Extending in this direction and originating in the region of the ampulla the diverticulum must of necessity be intimately related to the bile duct, which, as a rule, lies on the posterior or lateral wall, but the pouch may be actually constricted or rendered bifid by the common bile duct (Fig. 2); occasionally the bile passage opens on the fundus of the sac.

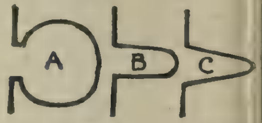
Fig. 2.



Relationship of diverticula to common bile duct (after Sir A. Keith.)

C.B.D. = Common bile duct.
R.D. = Right diverticulum.
L.D. = Left diverticulum.

Fig. 3.



Shapes of diverticula.

A, Flask-shaped. B, Cylindrical. C, Conical.

In size there is considerable variation, ranging from the size of a pea to that of a hen's egg, but most commonly of an intermediate size, about that of a walnut. At its duodenal opening the mouth of the pouch is usually comparatively wide and will usually admit the little finger, and may be still wider; from this origin the pouch extends outwards and may be flask shaped, cylindrical, or conical (Fig. 3).

The sac may be empty, and when exposed at operation becomes distended with gas. Instead of being empty, however, it may contain clear mucoid fluid, chyme, and (rarely) biliary sediment and bile-stained fluid, as in a post-mortem example recorded by Bassett,[14] in which the bile papilla opened at the lower lateral edge of the aperture of the pouch.

In structure the wall is thin; on microscopic examination, if the pouch is of the true type, it will be composed of all the layers of the duodenum, and the mucosa will show crypts of Lieberkuhn and Brunner's glands (Murchison's case[11]). More commonly, however, the diverticula are of the false type and composed of a mucosa, from which Brunner's glands are usually absent; the muscularis usually forms a well-defined ring at the base, but is deficient over the remainder of the sac, though sometimes a few fibres may be traced for a variable distance over the sac from the neck; occasionally a few atrophic fibres of the muscular coat cover the whole sac. Portions of pancreatic tissue may be found.

Frequency.—These diverticula are undoubtedly much more common than was formerly realised, and probably occur in from 1 to 2 per cent. of human subjects. Baldwin[15], 1911, found 15 diverticula in 115 cadavera. Linsmayer,[16] 1914, found 45 diverticula in 1367 autopsies (3·4 per cent.). Case[17] found 85 diverticula in 6847 X ray examinations (1·2 per cent.). Wyllys Andrews[18] found 26 deformities in 2200 X ray examinations (1·2 per cent.). Spriggs[8] found 10 diverticula in over 1000 X ray examinations. In about one-fifth of the cases the diverticula are multiple and there may be as many as five present.

Age.—Diverticula may be found at all ages from birth onwards, but much more commonly in old subjects; according to Buschi[5] 80 per cent. occur after the age of 50 years.

Pathological Conditions Superimposed upon Diverticula.

Although duodenal diverticula are much more equently present than was formerly imagined, yet thological conditions of these pouches are extremely re, either in the living subject or at necropsy. This ct is, undoubtedly, due to two factors—(*a*) the erility of the duodenal contents, and (*b*) the fact that ere is little tendency to stagnation on account of the de opening into the duodenum and the fluid nature the contents. Infection plus stagnation are the two eat factors in causing inflammation of diverticula, exemplified in the appendix and again in colonic verticula. The rate of emptying of duodenal verticula varies, and, as most frequently there is no usculature in the pouch wall, must of necessity pend largely on mechanical factors, and so be fluenced by the part of the duodenum from which the c originates and the direction it takes. Case,[17] from ray observations, states that the opening of the uch is usually so large that barium leaves almost as pidly as it enters. In a case reported by Basch[19] d operated upon by Elsberg, the pouch was dependent from the junction of the second and third rtions of the duodenum, and bismuth retention curred at the end of 96 hours; this case had sociated symptoms.

The pathological conditions which may be found e: (*a*) Of the diverticulum itself, acute or chronic lammation. (*b*) Results of the spread of inflamman, chronic duodenal catarrh, pancreatitis. (*c*) echanical results: interference with the passage of estinal contents giving rise to duodenal dilatation; struction of the biliary and pancreatic ducts.) Pathological conditions, giving rise to the formation the diverticulum.

Acute Inflammations.—These are rare. Bassett[14] corded a condition discovered post mortem of a uch filled with blood-stained fluid; microscopically e changes were those of a hæmorrhagic inflammation d there was an associated localised pancreatitis. 1919 Akerlund[20] reported a case in which the sac ntained a mass of necrotic pancreatic tissue, which d resulted from extension of the diverticulitis. low is reported a case, admitted as an emergency, in ich there was an acute inflammation of a thinlled friable sac with the mucosa entirely gangrenous.

Chronic Inflammations.—These are considered to be more frequent occurrence; a number of cases have en published in which the symptoms have been ributed to this condition, but as to how far these mptoms are actually due to these diverticula or to ier associated conditions it is difficult to judge at esent, as the pathological state has not usually been ntioned, any post mortem description being mainly ncerned with determining whether the diverticulum true or false.

Results of Spread of Inflammation.

Wilkie[21] in two of his three cases considered that gnation may have led to chronic duodenal catarrh; e of these cases, in which there were associated folds the duodenum, died of hæmorrhagic pancreatitis, e other had a number of associated pathological nditions—viz., duodenal ulcer, cirrhosis of the er, cholecystitis, and gall-stones. Inflammation eading from the diverticulum may involve the sely surrounding pancreas and give rise to a alised condition of chronic pancreatitis with ulting adhesions between the sac and the pancreas. example of such a condition is afforded in a female tient of Case's,[17] aged 45, who complained of pain the lower dorsal region. X ray showed a diverulum in which the food was retained a little longer an it took the stomach to empty. At operation a erticulum was found 5 cm. above the duodenounal flexure; it was not removed because of close hesions to the pancreas; appendicectomy and lecystectomy were performed.

Mechanical Results.—(*a*) Interference with the ssage of intestinal contents. Bauer[6] reported a se in which a large diverticulum of the second portion of the duodenum was thought to have pulled on the pylorus and to have caused persistent vomiting and emaciation; gastro-jejunostomy was performed but failed to stop the vomiting, and death occurred on the eleventh day. Post mortem there was dilatation of the stomach and of the duodenum above the site of the pouch. Similarly, in the case reported by Basch,[19] and operated upon by Elsberg, there was a dilatation of the duodenum above the diverticulum.

(*b*) Obstruction to the biliary and pancreatic ducts. Many of the cases of diverticula are associated with disease of the biliary tract and pancreatitis, as in the case of Wilkie's[21] above mentioned with associated gall-stones. This may be due to a mechanical obstruction of the ducts, or, as suggested by Akerlund,[20] due to a catarrhal inflammation giving rise to swelling and secondary dilatation of the ampulla of Vater, with insufficiency of the sphincter and so a pancreatitis.

(*c*) Pathological conditions associated. These may be either causative of the pouch—e.g., gall-bladder disease, duodenal ulcers, &c.—or merely accidentally associated.

Symptoms and Signs.

As a rule these pouches give rise to no symptoms, because there are rarely any pathological lesions of the diverticula. In cases of acute diverticulitis, as in the case reported below, the symptoms are the same as those of an acute inflammation of any diverticulum, and so will simulate appendicitis in association with an undescended cæcum, and the signs will correspond. In those cases in which the condition is not acute the symptoms will vary and consist of: (*a*) Those of accidentally associated conditions in which the pouch is discovered in the routine X ray examination; (*b*) those due to pathological conditions secondary to the diverticulum—e.g., duodenal obstruction with nausea and vomiting, biliary obstruction, and chronic pancreatitis; (*c*) those due to pathological conditions of the pouch itself. A typical case of this group is one reported by Lewis[22] in a patient who six years previously had an attack of pain two to three hours after meals relieved by the next meal. The condition then subsided, to be followed by a three years' history of pain in the right upper quadrant of the abdomen, radiating to the right shoulder and scapula, this pain coming on two to three times a week. The onset of the pain was gradual, becoming worse during the course of the day and reaching its height at about 5 P.M.; there was occasional nausea and occasional jaundice. Operation showed a diverticulum on the anterior wall of the first stage of the duodenum, and its removal yielded relief of symptoms. Moore[23] also records a case in which the main symptom was pain coming on late after meals, and observes that the pain was worse in the afternoons; this may possibly be due to the pouch filling during the day and emptying during the night.

Other symptoms are nausea, flatulence, "sour stomach," distension, and fullness. It will be seen that such pouches may give symptoms simulating the other surgical dyspepsias—e.g., gall-stones, duodenal ulcer, &c.

Treatment.

As a rule treatment is not required because of the lack of symptoms. On the other hand, if these diverticula are discovered during a barium meal examination of a patient, who is complaining of abdominal symptoms, their removal is indicated. If possible, X ray localisation should be careful and accurate, as otherwise great difficulty may be encountered in finding a retro-peritoneal pouch at operation. The treatment is—(1) invagination of the diverticulum if small, or (2) excision if too large for this form of treatment. On account of narrowing of the lumen of the bowel as a result of excision it may be necessary to combine with the above a gastro-jejunostomy, or, if the pouch is of the third portion of the duodenum, a duodeno-jejunostomy. Occasionally the diverticulum may arise from the first stage of the duodenum and be combined with a pyloric ulcer, as in Murchison's case,[11] when the pylorus and the first portion of the duodenum were removed and anastomosis performed. Mr. Walton's case quoted above affords a similar example.

Case Record.—Married woman aged 27; occupation, household duties.

Past History.—Influenza. No history of indigestion of any description.

Present Illness.—Onset March 20th, 1923, at 1 P.M. Abdominal pain in epigastric region, of a dragging character and giving rise to a feeling of nausea. Later the pain settled in right hypochondrium. Vomited four times.

Progress.—On the 21st, at 3 A.M., pain became worse and persisted until 8 A.M., when it lessened somewhat. Bowels regular; micturition not affected.

Condition on Admission.—Thin woman with a sallow complexion. Temperature 101·3° F., pulse 108 per minute. Abdomen: Marked tenderness and rigidity of the upper half of the right rectus muscle; no palpable tumour; muscles of lower right abdomen flaccid. Hyperæsthesia nil. Urine, heart, lungs, and nervous system, nothing abnormal discovered.

Pre-operative Diagnosis.—Acute inflammation of a vermiform appendix situated under the liver.

Operation.—At 9.45 P.M. on the 21st, under general anæsthesia (A.C.E. and ether), by Mr. W. Thomas. No tumour palpable. Right paramedian incision 4 in. in length, extending upwards from the umbilicus. The cæcum came up freely into the wound and the appendix appeared normal. The appendix was removed. A flake of lymph was observed to come down from the right upper abdomen. On prolongation of incision upwards, the stomach, gall-bladder, and first stage of duodenum were found to be normal. In the area between the duodenum and the gall-bladder and situated on the posterior abdominal wall was a lump, surrounded by an area of infiltration and œdema, and situated in front of the kidney, which could be moved behind it. The gastro-colic omentum was opened and the pancreas found to be apparently normal. An incision was made through the posterior peritoneum above and to the outer side of the duodenum; it was then possible to separate out a pouch from the retroperitoneal tissues. This pouch had a diameter of 1 in., and was thin-walled and black in its centre. (Fig. 1 shows a section of the apex of this diverticulum.) The mucosa was black; the pouch was empty except for a small amount of friable golden-yellow debris; in the lower portion there was a communication into the duodenum in the region of the ampulla of Vater which would admit the little finger. The diverticulum was not connected with the bile ducts. It was cut away, the neck being sutured with a running catgut suture; an endeavour being made to put in a second invaginating suture, bleeding occurred from the inner portion of the neck, and this suture had to be abandoned and the bleeding controlled. The posterior peritoneum was sutured as best possible, but was extremely friable. Stab drainage laterally. Abdomen closed in layers and with tension sutures.

Progress.—Three days after operation the stab wound started to discharge freely and there was a fistulous communication. On the tenth day the stitches were removed, the laparotomy wound having healed by first intention; discharge from the stab wound was diminishing. On the seventeenth day the discharge had ceased and the stab wound was granulating. Patient was sent to convalescent home on twenty-first day.

In conclusion, my thanks are due to Sir Hugh Rigby and Mr. A. J. Walton for kindly giving me permission to publish their cases.

FURTHER RESEARCH ON THE RELATION OF CARCINOMA TO INFECTION.

BY W. M. FORD ROBERTSON.

IN a paper by my late father, Dr. William For Robertson,[1] read before the Section of Pathology an Bacteriology[2] of the British Medical Associatio Newcastle-upon-Tyne, July, 1921, he recorded tha certain rods which he had observed within cance cells were anaerobic bacilli of the diphtheroid grou of micro-organisms. Further, he brought forwar evidence to show that the continued proliferation the epithelial cells was due to the action of thes bacteria.

As stated in the paper there are, at least, fou distinct methods by which the validity of th hypothesis might be tested: 1. Direct microscopi examination of cancer cells. The rods were demor strated many years ago (THE LANCET, Jan. 28th, 190 by my father's palladium methyl-violet method they occur chiefly within the nucleus and the infecte cells occur in special areas; throughout the greate part of the tumour it may be impossible to observ any of these rods. 2. Artificial cultivation of th supposed bacteria. The evidence of this kind obtaine up to the time at which the paper was published, a pointed out by the author, was, "perhaps not s decisive as that of the other three methods," bu was sufficiently striking. He had isolated anaerobi bacilli of the diphtheroid group from eight carcinomat of the breast. It is to fill up this gap in the evidenc then put forward that the present research ha been undertaken. 3. The experimental production c cancer. Either pure cultures of the anaerobi diphtheroid bacillus, or of cultures of this micro organism, together with cultures of a staphylococcu obtained from the human cases investigated, wer inoculated into mice. Carcinomata were produced i one series of cases, positive results being obtained i all (100 per cent.) of five mice inoculated by th anaerobic diphtheroid bacillus and a mannite non fermenting staphylococcus obtained from the sam human case of adeno-carcinoma of mamma. In thi experimental work it was recorded that micro organisms obtained from a cancerous growth in th human subject produced cancerous growths, primar in various organs (kidney, pancreas, uterus, &c.) c the different mice inoculated. 4. Focal reaction an therapeutic immunisation. Several cases of huma carcinomata were recorded in which definite focal an general reactions occurred after inoculation with vaccine prepared from the diphtheroid bacillus. O certain of these cases, after such vaccine treatment, th neoplasms had decreased in size, the pain and dis comfort from the growth were greatly diminished One case of recurrence after operation was treated, th recurrent growths disappeared, and, at the presen time of writing (July, 1923), the patient is still aliv active, and able to pursue his occupation, that of labouring man.

To complete the cultural evidence it was obviou that a modification of the methods employed up to th date of the paper at the end of 1921 was necessary Dr. Ford Robertson introduced into his technique th de-aeration of pure sheep's serum and, also, o de-aerated hæmoglobin serum glucose agar medium

Before the value of these media could be teste thoroughly Dr. Ford Robertson was taken ill, and th work was carried on by me. The present paper is record of this work.

Throughout my investigation I was in constan personal communication with my father, and, as result of my work, both cultural and therapeutic, h requested me, shortly before he died, to state that h was convinced that the cause of and a cure for cance d been discovered. The laboratory findings orded in the present publication were demonstrated the Section of Pathology and Bacteriology at recent annual meeting of the British Medical sociation.

---

[1] An obituary notice of Dr. W. Ford Robertson appeared i THE LANCET of July 28th.—ED. L.

[2] THE LANCET, 1921, ii., 335; Brit. Med. Jour., 1921, ii., 929.

Preparation of Media.

1. *Preparation of De-Aerated Sheep Serum* (*D.A.S. edium*).—For many years Dr. W. Ford Robertson pt a small flock of sheep solely for the purpose of taining blood or serum. A large hollow needle ving been sterilised in boiling vaseline, the excess of seline is shaken out, and the needle is transferred to a rile test-tube which is plugged. The sheep is iced and secured on a trestle sufficiently high to keep feet off the ground. The side of the neck is pped, lathered, and shaved. The wool around the ved part is soaked with a solution of carbolic acid d the shaved skin cleansed with 1 : 50 (about) rbolic acid. The external jugular vein is made to nd out prominently by pressure applied to the ver end. The large sterile needle is inserted into the in at its upper end, and the blood is allowed to w through the needle into 6 in. by 1 in. test- bes, about 40 c.cm. of blood being collected in each be. Twelve tubes are taken at each bleeding. The od is allowed to stand for not more than 24 hours, d then the serum is pipetted or drained off. Any be in which the serum is cloudy and showing a m on the surface is discarded (*Bacillus subtilis* is the st frequent contamination found). Some of the bes occasionally have shown a fatty layer floating on surface of the serum after 24 hours. This is thick d creamy in character, being quite distinct from cloud and scum produced by *B. subtilis*. After canting the serum into sterile test-tubes of ordinary e (5 in. by ½ in.), each of which is half filled, the fatty stance may continue to appear. As many as four trifugings have had to be done in order to clear serum. The centrifuged deposits have been croscopically examined and proved to consist of fat bules, all inoculations from these deposits on to moglobin agar, &c., have proved them to be entirely e from micro-organisms. The ordinary tubes are gged lightly and then transferred to an air-tight ttle attached to a Geryk pump. Air is exhausted til the serum begins to froth, further air being racted when this frothing has ceased. The process repeated every 15 minutes throughout the day. e tubes are incubated in vacuo until required for , a periodical examination being made for the sence of cloud or marked deposit. Any so ected are centrifuged and tested for sterility. the serum remains clear from the beginning, con- nination rarely occurs later if care is taken with plugging before storage. The presence of the fat, wever, may give a little trouble, but this merely uires the serum to be centrifuged and the clear d decanted into a fresh sterile tube. In some es it has been found useful to acidify the de-aerated um by bubbling CO_2 gas through it for five minutes A.S. + CO_2). When required for use the de-aerated ep serum is decanted into small tubes measuring n. by ¼ in., which are sealed with corks soaked with ling paraffin wax.

. *Preparation of De-Aerated Hæmoglobin Serum cose Agar* (*Glucose Agar* + 12).—After pouring off serum from the blood in the large tubes as cribed above, the blood-clot is allowed to stand for rther 48 hours. To produce lysis of the corpuscles tubes are kept overnight in a freezing mixture of and water, after which they are warmed up in a in of water at 60° C. for 10 minutes. They are n kept 24 hours before decanting into large sterile es. The hæmoglobin serum is then de-aerated by same method as described for de-aeration of the e serum. Freshly sterilised agar, in a test-tube of inary size, is cooled down to about 70° C., and a drops of the de-aerated hæmoglobin serum are led and mixed. The tubes are sloped and the tents allowed to solidify. A sterile cotton-wool g, half an inch in length, is pushed down to just ve the upper limit of the agar. A small amount of pyrogallic acid is shaken on to the top of the plug, a few drops of sodium hydroxide solution (10 per cent. in water) are added, and the test-tube is sealed by a cork soaked in boiling paraffin wax. The tubes are incubated at 37° C. for 24 hours to test their sterility, and are then stored for use. The glucose agar is made according to the technique given in "Therapeutic Immunisation in Asylum and General Practice," by W. Ford Robertson, Chap. V., "Bacteriological Methods." The acidity of the agar is + 12.

3. *Other Media Used.*—Other media used have been made according to the instructions contained in "Therapeutic Immunisation in Asylum and General Practice" referred to above. In some cases Dorset egg medium has been made with the addition of de-aerated hæmoglobin serum, and has proved a valuable medium in the research. In several instances, to obtain the earlier subcultures, Dorset egg medium was necessary.

Technique for Inoculation of Media.—A small cube of about ½ in. square is cut out with strict aseptic precautions from the deeper margin of a neoplasm removed at operation. Culture must be made not later than 8 to 12 hours after operation. With lymphatic glands containing metastatic growths the whole gland may be used if small enough. The cube removed is cut up into small portions of such size as to be capable of insertion into the 2 in. by ¼ in. test-tubes. (*a*) One of these portions of tissue is pushed down with a sterile glass rod into each of two D.A.S. tubes and into two D.A.S. + CO_2 tubes until it is just below the surface of the medium. The paraffin cork is re-heated and re-inserted. The tubes are then incubated at 37° C. (*b*) The remaining pieces of the tissue are cut up into small fragments and placed in a strong test-tube containing ¼ inch of sterile ground glass. About ½ in. of sterile normal saline solution is added and the whole ground up by a sterile glass rod. A few loopfuls of this solution are used to inoculate the following media: (1) One or two tubes containing "glucose agar + 12" medium and rendered anaerobic by the pyrogallic acid method (see above). (2) One tube containing Dorset egg medium; after inoculation the air is displaced by CO_2 gas and the tube is sealed with a plug of wool soaked in hot paraffin. (3) Instead of tube (4) in some cases Dorset egg medium, to which had been added de-aerated hæmoglobin serum (see above) is used. After inoculation the air is displaced by CO_2. (5) Two tubes containing ordinary hæmoglobin agar + 18. One of the tubes is rendered anaerobic by the pyrogallic method, the other being incubated anaerobically. (6) One tube containing ordinary lactose serum agar incubated aerobically. All these tubes were incubated at 37° C.

Addendum on Technique.—Recently a modification of the cultural technique has been employed which has proved of great use in making early subcultures and in dealing with weekly growing strains of the anaerobic diphtheroid bacillus. This technique was devised to bridge over the gap existing between the fluid D.A.S. and D.A.S. + CO_2 media and the comparatively dry condition of the surface media in the glucose agar + 12 tubes, the transition from one to the other being too sharp. A small amount of D.A.S. was poured into a tube containing glucose agar + 12 medium sufficient to form a layer 1 mm. thick and allowed to collect at the bottom. The surface of the tube was then inoculated with a loopful or more of the deposit. A small sterile plug was next inserted and pushed down a short distance from the upper limit of the medium. On this plug a layer of ⅛ in. finely powdered calcium chloride was dropped, which was covered by another sterile wool plug ½ in. in thickness. On this plug a thin layer of pyrogallic acid was laid, and a few drops of sodium hydroxide (10 per cent. sol.) was added. The mouth of the tube was then sealed with a cork previously soaked in boiling paraffin wax. The tube is now laid flat, so that the serum formed an even layer over the medium, the whole being incubated for 36 hours. After this time the calcium chloride has absorbed all the water from the serum and a dry or sticky surface is left. The tube can be incubated in a vertical position. This method has been found valuable also in increasing the vigour of pure anaerobic growths after prolonged subculture and incubation. Three different strains of anaerobic diphtheroids from separate cases have been restored to vigour by this means.

Examination of Culture Media.

All the inoculated tubes (1) to (6) inclusive in the previous paragraphs were examined for growth after 24 to 48 hours' incubation. Those tubes showing no visible growth, or only a sparse growth, were replaced in the incubator. From those tubes in which there was a copious growth, films were made and stained by Gram-neutral red method and examined microscopically. A note was made as to the group of micro-organisms (streptococci, staphylococci, &c.) present, but no further investigation of these was made except in those particular instances in which subsequent examination of the anaerobic diphtheroid bacillus, subcultured from the D.A.S. culture, showed micro-organisms resembling somewhat streptococcal forms. In such cases any streptococcal colonies and suspected diphtheroid colonies were subjected to a series of biochemical tests to differentiate the species (lactose, mannite, salicin, and lactose serum broth).

With reference to the D.A.S. and D.A.S. + CO_2 tubes it was found that the time required for primary incubation varied according to the malignancy of the neoplasm. The more malignant the tumour, the shorter the time required before examination. For example, in the case of a rapidly growing epithelioma, the anaerobic diphtheroid bacillus was found in enormous numbers after four days' incubation at 37° C., whereas, in an atrophic scirrhus, after one week's incubation at 37° C., comparatively few diphtheroid bacilli were present. In some cases the serum in the tubes became cloudy owing to the presence of streptococci, but these tubes, as well as those in which the serum remained clear, showed a white deposit varying greatly in amount. A loopful of the deposit, or if the latter was copious, a little removed in a capillary tube, was used to make a thin film. It was found better to dilute the serum on the slide with distilled water, to avoid too deep staining of the background. The film was stained by Gram neutral red. As in any film containing serum, decolorisation by alcohol was continued only until the violet stain ceased to stream away. If an attempt was made to decolorise the background completely all the micro-organisms on the film would naturally be decolorised. Further, the gentian-violet solution was filtered on to the preparation. It was found that the white deposit consisted of bacteria and disintegrated tissue. Often partially disintegrated epithelial cells were seen. The background consisted of a very finely granular field which should not be mistaken for micro-organisms and is present in films made of uninoculated serum. The amount of white deposit was found to have a relationship to the numbers of micro-organisms present other than the anaerobic diphtheroid bacillus. The greater the number of streptococci, staphylococci, &c., present, the larger the deposit. The growth was then subcultured from the primary growth in D.A.S. and D.A.S. + CO_2 media. The white deposit in the primary D.A.S. and D.A.S. + CO_2 culture was used to inoculate the Dorset egg + CO_2 medium and G.Ag + 12. Two tubes of each of these media were used. These subculture tubes were incubated at 37° C. The colonies of the diphtheroid bacillus were visible on the egg medium after three to seven days, but, owing to delay in examination, consequent on the large number of tubes dealt with, the colonies had, in some cases, become quite large when first examined. Further subcultures were made to obtain the anaerobic diphtheroid bacillus in pure growth. The media used for these subcultures were either Dorset egg medium + CO_2 or glucose agar + 12 according to the medium on which the first subculture of the particular strain had grown best. For study of characteristics of colonies and picking of them off for pure subcultures, a strong hand-lens was used with double-jointed movable spring clip. The clip attaches the lens to the tube, thereby allowing the apparatus to be slipped along the tube and focused easily on any particular colony. The tube with clip attached is held in the left hand, and the platinum needle is inserted and a colony picked off under the lens.

Cultural Characters and Morphology of the Anaerobic Diphtheroid Bacillus.

In pure cultures on Dorset egg medium + CO_2, to which a few drops of alcoholic solution of basic fuchsin have been added, after 24 to 48 hours the colonies, as seen through a strong hand-lens, appeared as minute rounded, semi-transparent, white or pinkish growths. In those cases in which the colonies were pinkish the colour was due to the bacilli having taken up the stain, as when removed by the platinum needle the colony on the needle showed the pinkish coloration. The colonies were soft and slightly sticky, except in one case in which the culture was first examined after six days, and showed soft colonies and colonies which were granite-like and very difficult to break up.

In pure culture on glucose agar + 12, after 24 to 48 hours, the colonies as seen under a strong hand-lens, appeared as minute round transparent moist colonies. Subsequently as they increased in size they became semi-transparent and later yellow or greenish-yellow, while the medium became cloudy and dirty brown. Again, other species took on a pink coloration, with very little change in the medium. After about two weeks' incubation at 37° C. the colonies were the same dirty-brown colour as the medium.

Films of the anaerobic diphtheroid bacillus made from cultures show it to be an incompletely Gram-fast rod. In de-aerated serum the micro-organism occurs singly and in clumps, its length varying from 0·5 to 2 microns, its breadth being 0·2 micron. On Dorset egg medium + CO_2 and on glucose agar + 12 the micro-organism frequently shows pleomorphism. Numerous short coccoid forms occur, these being found sometimes in chains of five or six elements. The elements forming the chains are connected by a faintly staining filamentous sheath. Small rods in short-chain formation, with or without connecting filamentous sheath, occur. Some strains are uniformly longer rods 1·5 to 2 microns in length; curved and V-shaped forms are seen also. Other strains are uniformly short, being 1 micron in length. Bacilli with a thick club-shaped extremity and bacilli with a bulbous centre occur occasionally, especially in old cultures.

Material Examined.

The series examined in the present research consists of 15 cases of malignant disease. It comprises six cases of adeno-carcinoma of the mamma, three being scirrhus and three being encephaloid in type: One case of primary liver-celled carcinoma and the discharge from the wound after operation, one case of squamous-celled carcinoma, metastatic in submaxillary lymphatic gland, the primary neoplasm being from the lower lip; one case of carcinoma of the maxillary sinus; one case of sarcoma of the maxilla; one case of adeno-carcinoma of rectum; one case of adeno-carcinoma of the ovary, papilliferous in type; one case of squamous-celled carcinoma of cheek; one case of squamous-celled carcinoma of glans penis; swab from squamous-celled carcinoma of the cheek. From all these 15 cases the anaerobic diphtheroid bacillus has been demonstrated in cultures. In seven cases the bacillus was obtained subsequently in pure cultures in sufficient quantity for vaccines to be prepared and used therapeutically. The results obtained by this vaccine treatment will be published later. In all 15 cases a mannite non-fermenting staphylococcus was isolated, and in about two-thirds of the series streptococci were present also. In nearly every instance these staphylococci and streptococci were obtained only in anaerobic cultures. Two control cases were examined. In one case subcutaneous fat, and, in the other case, muscle of patients who were not the subject of malignant disease, gave negative results for the anaerobic diphtheroid bacillus.

I wish to express my gratitude to the various urgeons in Edinburgh and in Dunfermline, who have upplied me with material for this investigation, and specially to Mr. George Chiene and to Mr. Pirie Watson, who have given me every facility for arrying out the work. I am indebted also to Mr. Becker for his great kindness in helping me to collect he material, and to Dr. Batty Tuke for the interest e has shown and the encouragement he has iven me.

Reviews and Notices of Books.

HEREDITY AND EUGENICS.

By R. R. GATES, Ph.D., Professor of Botany in the University of London. London: Constable and Co. 1923. Pp. 288. 21*s*.

THIS entertaining book should be closely read by all vho are interested in human inheritance, especially f they approach the subject with the idea of doing omething to make man better than he is. After a eneral introduction the author gives a pretty full ccount of what is known about the inheritance of bnormalities in man, a long discussion on twins and heir resemblances, and concludes with a survey of he mass of questions involved in "eugenics" and population." There is a good bibliography of books nd papers. Two conclusions come out particularly rominently.

In the first place, it is plain that there are many oors of human inheritance which the key of Mendelism 1 its simplest form will not unlock, and when Iendelism passes on to reversed dominance, multiple actors, and such like, the practical sociologist may well eel that the problem is more difficult than he thought was. It is well that he should do so, for there has een much easy talk in recent years of the possibility f the regeneration of man if only geneticists could ave their way. Left-handedness, for example, was riginally found to be a simple Mendelian recessive haracter. More recent investigation has, however, iggested that the mode of inheritance is not altogether lear, and that right- and left-handedness are not lternative characters but in their most marked forms ne ends of a series with a large number of intermediate gradations—i.e., that many factors are ivolved. In the second place, one is impressed by the ict that even if the modes of inheritance of undesirable and desirable human qualities were known, it ould be by no means an easy matter to eradicate or ıltivate them unless the character in question is a mple dominant with a single factor. There is no articular reason for abolishing bradydactyly, but as is a simple dominant character it could be kept nder by preventing anyone who showed it from reeding and keeping a close watch for its possible eappearance de novo.

But musical ability and feeble-mindedness are cessive characters, and when the homozygous have een mated together or sterilised as may be appropriate ie human breeder has still to deal with the heterozygous individuals who are carrying but not showing ie character. It is reckoned, for example, that in the nited States about 3 per 1000 of the population are entally defective, and that at least 70 per 1000 are ırrying mental deficiency as a recessive character. the former mate together there is a certainty of efective children; if two of the latter happen to arry—and the chance is obviously not a very small ie, even if cousin matings are barred—a quarter of ieir offspring will be defective. As Prof. R. C. Punnett is pointed out, it would take some 250 generations, about 8000 years, to reduce the feeble-minded from per 1000 to 1 per 100,000 by simply segregating or erilising those who show the character. And when comes to characters which are not single factors, ie complications seem almost insuperable. Truly it ems sometimes that the function of natural knowdge is to explain why things are as they are without ving us any easy way by which to make them better. No doubt in the end it will be possible to do a good deal, but the time for action on a large scale has certainly not arrived yet.

An interesting discussion of the effects of racial interbreeding points out that in fact very few detailed studies have been made; such information as there is suggests strongly that the miscegenation of races which are far apart in the scale of social and intellectual development or markedly dissimilar physically is likely to give results which are in general bad, owing to a disharmonious mixture in the offspring violating the unity and wholeness which are characteristic of a perfect individual. The colour question needs clear thinking in all its aspects; it appears that facts to think about are wanted even more. Many of the qualities which future generations will value most highly may well be recessive.

HERNIA AND ITS RADICAL CURE.

By J. HUTCHINSON, F.R.C.S. Eng., Consulting Surgeon, London Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 264. 12*s*. 6*d*.

THE frequency with which operations for hernia are nowadays performed has led to the difficulties being sometimes under-estimated, and we must admit that a few years ago hernia operations on soldiers were followed in too many cases by recurrence and other complications that could have been avoided by more careful and accurate methods. Mr. Hutchinson's book is therefore doubly welcome, for from the fruits of a wide experience he has made it his aim to give a practical account of hernia and the best methods for its radical cure. Many of the technical details that the author describes have been originated by himself, and while his methods are mainly in accordance with those used by the majority of British surgeons, he describes fully the less orthodox methods of others; in this way a thoroughly up-to-date account has been produced, and comparisons of various procedures are made in a fair and broad-minded spirit.

Mr. Hutchinson does not hold the view that the majority of inguinal hernias have a congenital origin, and he considers that nearly all umbilical and femoral hernias are acquired. A full and valuable account is given of the contents of hernial sacs, and special interest attaches to the sections on hernia of the vermiform appendix and of the urinary bladder, and on the various forms of fatty hernia. In inguinal hernia, where there is a well-developed conjoined tendon, the author sutures this tendon in front of the cord to the external oblique just above Poupart's ligament, thus allowing the cord to remain in its normal bed formed by that ligament; if the conjoined tendon is poorly developed Halsted's operation is preferred. The difficulties and dangers of operation for recurrent inguinal hernia are dealt with and, many exceptions being admitted, the general rule is laid down that it is better not to operate again where a suitable truss effectively controls a recurrent inguinal hernia. For imperfect descent of the testicle early operation is advocated, the testicle being brought down to the scrotum; the means of keeping it there are indicated. In femoral hernia the author is accustomed to operate from below and to suture Poupart's ligament to the pectineus fascia, but he also describes and discusses fairly Lotheisen's method that has become popular among so many other surgeons. For umbilical hernia Mr. Hutchinson describes his own method of closing the abdominal wall by two rows of sutures, the first a layer of mattress stitches taking tension off the second row. He is a firm advocate of the use of kangaroo tendon sutures, and he brings forward evidence to show that these are not absorbed but become incorporated in the body as firm fibrous tissue, with considerable advantages over catgut on the one hand, and such substances as silk and silkworm gut, which persist as foreign bodies. Metal filigrees are condemned and the author's opinions are confirmed by the increasing rarity with which such materials have been employed in recent years. The diagnosis and treatment of strangulation are well described; where resection is necessary Mr. Hutchinson advises delivery of the bowel through a separate abdominal incision and he is in favour of end-to-end anastomosis.

The interest and value of the book are enhanced by the frequent descriptions of unusual cases and the numerous references to recent literature; its size has been limited by the omission of such details of anatomy, differential diagnosis, and treatment by trusses as have received full attention in many text-books; instead, the author has devoted himself primarily to a detailed account of the operative measures which in his large experience he has found suitable to all the different forms of hernia. As he writes clearly and his technical descriptions are easy to follow and well illustrated by diagrams, Mr. Hutchinson has fulfilled his object of producing a book of value to surgeons on a subject of considerable importance to the community.

The Mechanism of Facial Expression.

Der Gesichtsausdruck und seine Bahnen, beim Gesunden und Kranken besonders beim Geisteskranken. By Prof. Dr. Theodor Kirchhoff in Schleswig. Berlin: Julius Springer. 1922. With 68 illustrations. Pp. 227. 9*s.*

The clinical part of this interesting monograph is peculiarly full and detailed; that dealing with pathological physiology is somewhat unsatisfactory. Prof. Kirchhoff apparently accepts without criticism the view that a second (non-pyramidal) facial path exists, extending from the cortex to the thalamus and from the latter ganglion to the nucleus ruber and so by rubro-pontine paths to the facial nucleus. This "affektbahn," however, is, to say the least, problematical. Many difficulties connected with the assigning to the optic thalamus of the function of emotional expression are not, we consider, sufficiently tackled by the author, who relies largely on observations now somewhat old, and does not, in our opinion, meet successfully the objections raised by Roussy to a thalamic localisation for emotional play of feature. The monograph is none the less instructive and readable, and supplies in convenient compass a great deal of clinical material of interest both to psychiatrist and neurologist.

The Corneo-Scleral Dome.

La calotte cornéo-scleral. By Dr. F. Terrien, Ophthalmologist to the Beaujon Hospital, Paris. With 144 figures. Paris: Masson et Cie. 1923. Pp. 260. Fr.25.

This treatise appears as one of a series entitled "Sémiologie Oculaire." The same author has previously written a work on the surgery of the eye and its annexes, and in attempting to deal solely with the anatomy, physiology, and pathology of the anterior part of the globe has set himself a somewhat thankless task. As far as conjunctival infections go, they can, it is true, be dealt with satisfactorily without reference to the rest of the eye, and this is perhaps also true of superficial affections of the cornea. Interstitial keratitis, however, may or may not be attended by inflammation of the iris and choroid, and the sign popularly known as "keratitis punctata" is always the result of a cyclitis. Again, penetrating wounds of the cornea involve the possibility of prolapse of the iris, of traumatic cataract, and of the presence of a foreign body in the globe. All this necessitates considerations which go far deeper than the corneo-scleral dome, and accordingly, in this treatise, we have the radiographic diagnosis of foreign bodies and the methods of their extraction by the giant, and by the small electro-magnet. Similarly, the proper treatment of serpiginous ulcer of the cornea cannot be carried out without a knowledge of the bacteriology and surgery of the lacrymal sac. These facts are not ignored, but they are perhaps hardly given their due weight in this book. Looking for compensating advantages in Dr. Terrien's method of approaching his subject, we find a useful description of the examination of the cornea in the living subject by the corneal microscope and slit lamp, and an excellent figure showing the magnified vessels, both blood and lymph, of the limbus. The bulk of the book, however, resembles chapters out of an ordinary text-book. Terrien can write most interestingly of his own original observations, as in his book on oculo-orbital sequelæ, but in this book the advantages over the average full text-book are not very apparent.

Inflammation of Bones and Joints.

By Leonard W. Ely, M.D., Associate Professor of Surgery, Stanford University. London and Philadelphia: J. B. Lippincott Co. 1923. Pp. 433. 30*s.*

The treatment of diseases of joints has advanced but little of recent years, so that we turn to a monograph dealing with this branch of surgery with some interest. Prof. Ely's book treats of bone diseases as well as affections of joints. On the whole it is disappointing. In bulk it occupies considerably more space than is devoted to these subjects in the ordinary student's text-book of surgery, yet the reader will get little more help and information from it. Splints and apparatus are scarcely more than mentioned; there is no detailed description of their application. There is no account of the filling of bone cavities with pedicled muscular or with fat-grafts, nor do we find any reference to Wilms's method of treating septic joints. The author ascribes the localisation of bacteria in the ends of bones to the marrow in this situation being of a particular type, the lymphoid type, but he leaves only a vague impression as to what he really means by this. Speaking of the diagnosis of tuberculous joints, he points out that many non-tuberculous joint infections have on clinical grounds been regarded as due to the tubercle bacillus, and that such a diagnosis can only be established with certainty by the demonstration of the organisms in the joint fluid or synovial membrane. Prof. Ely's views on the influence of age upon the treatment of tuberculous joints are interesting and worth further investigation. He believes that this infection only attacks the synovial membrane and the lymphoid marrow of the bone-ends. Whilst it is possible to remove these two tissues in adults, it is quite impossible in children. Therefore, in adults resection should be the rule. Loss of joint function leads to disappearance of synovial membrane, a change in the marrow of the adjacent bones, and an inability of the disease to progress. He is satisfyingly frank about the results of our treatment in certain cases of chronic rheumatoid arthritis, stating that no known remedies can influence the course of the disease in the slightest. Admissions of this kind do much to stimulate the investigation of those hopeless diseases against which our present knowledge cannot prevail.

Kala-Azar.

A Handbook for Students and Practitioners. By L. Everard Napier, M.R.C.S., L.R.C.P. Lond., in charge of Kala-azar Research, Calcutta School of Tropical Medicine; and Ernest Muir, M.D., F.R.C.S. Edin., of the Calcutta School of Tropical Medicine. London: Humphrey Milford. Oxford University Press. 1923. Pp. 160. 8*s.* 6*d.*

This handbook represents an elaboration by Dr. Napier of a somewhat similar, but smaller, volume written by Dr. Muir several years ago. The objects of the present volume are twofold: to record briefly and concisely the facts of the disease as at present known and to indicate the lines on which future research should be conducted, especially as regards the transmission of the disease. The three principal foci of the disease in India are Assam, Bengal, and Madras; on the other hand, Burmah, Ceylon, Bombay, the Punjab, and the N.W. Frontier Province have only recorded imported cases. To all intents and purposes, though the disease occurs in other parts of the tropics and subtropics, kala-azar is essentially an Indian disease, and its complete elucidation a matter of primary mportance to that country. This book, then, fulfils n admirable purpose in setting forth succinctly all hat is known about the disease as it occurs in India. The section dealing with the pathology of the blood, describing the formaldehyde test, or the formol-gel reaction, which may be taken as absolutely diagnostic of kala-azar, is specially to be commended. Spleen puncture is regarded as a perfectly safe operation, we are glad to note, but there appears to be nothing to recommend sternum puncture as a means of investigating the bone-marrow with a view to diagnosis. The clinical descriptions and the methods of treatment are particularly complete and are, therefore, welcome o the sincere student of tropical medicine. While strongly advocating the specificity of antimony tartrate in this disease, the authors are careful to express the opinion that finality has by no means as yet been reached, and that the future is dependent upon investigations upon the pharmacology and biochemistry of the antimony salts. In regard to these aspects of treatment little, if any, investigation has as yet been attempted.

THE new edition of Delafield and Prudden's ‘Text-book on Pathology," reviewed last week in this olumn, is published in England by Messrs. John Bale, Sons nd Danielsson, Ltd.

JOURNALS.

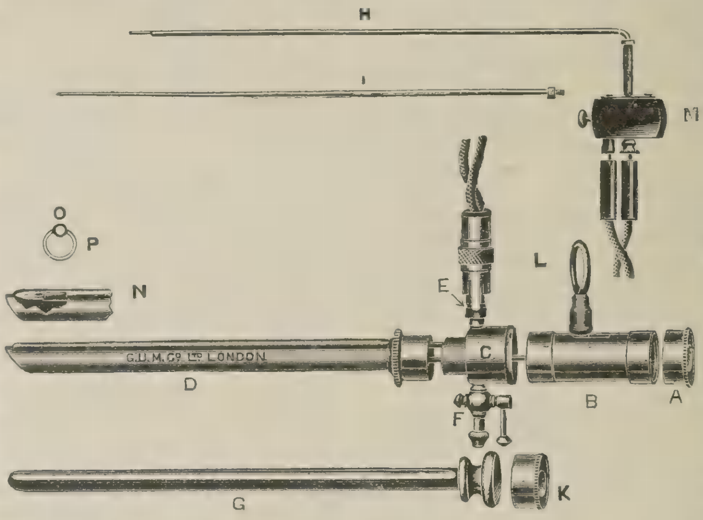
BRAIN. Vol. XLVI., Part 1.—On Certain Tonic or Postural Reflexes in Hemiplegia, with Special Reference o the so-called "Associated Movements," by F. M. R. Walshe. Continuing his brilliant researches into the phenomena of hemiplegia the author analyses a series f cases showing the so-called "associated movements." He concludes that they are tonic or postural reflex actions allied to the tonic neck and labyrinthine reflexes of Magnus and de Kleijn. They are best elicited by tonic voluntary activity of the normal limbs, nd in these circumstances may be described, following Magnus's nomenclature, as "tonic reflexes arising in he limbs and acting on the limbs." The point illustrated by associated reactions, whatever their place f origin and seat of response, is that while the tone of given muscle depends primarily and essentially upon he integrity of its own afferent supply, yet this tone is onstantly influenced and modified by impulses arising n proprioceptive end-organs elsewhere in the body.—The Oculomotor Nucleus of Tarsius and Nycticebus, y John I. Hunter. They exhibit the presence of a entral nucleus of Perlia which is smaller than in the nthropoidea. The Edinger-Westphal nucleus is in ach case single; it is also concluded that relatively ew optic fibres fail to cross in the optic chiasma. hese differences from the anthropoidea are believed o indicate that stereoscopic vision has not yet been properly attained.—Lethargic Encephalitis and Herpes ebrilis, by Z. Szymanowski and Nathalie Zylberlast-and. By inoculation of the cornea of rabbits with aterial from the idiopathic herpes and from herpes ssociated with cerebro-spinal fever and scrofulosis the uthors produce evidence to show that the pathological hanges in the brain resulting therefrom are identical ith those due to encephalitis lethargica. As a control ther rabbits were inoculated with the virus of ncephalitis lethargica itself. It is interesting to note hat these observers found inflammatory changes in he liver in all their animals, whether inoculated with erpes or with encephalitis lethargica.—Dystrophia yotonica (Myotonia Atrophica), by W. J. Adie and G. Greenfield. A brief review of the history of this sease is given together with a full description of an utopsy, believed to be the first to take place in this ountry, and a description of the disease based upon cases observed by the authors. They conclude hat dystrophia myotonica is a disease *sui generis* ithin the group of heredo-familial degenerative sorders. The fully developed disease is confined in he main to one generation (the dystrophic generation) here it occurs in some members of a number of milies of the same child-rank to a common ancestor. this generation some members remain healthy, some may have cataract alone, some may suffer from the disease in an incomplete form; whilst others present the combination of muscular atrophy and myotonia with certain extra-muscular symptoms for which the name dystrophia myotonica has hitherto been reserved.—Iron in the Brain, by A. Gans. A description is given of the various methods of obtaining the iron reaction in the brain together with some results obtained, with the object of directing attention to the importance of this promising method of research.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXVI., No. 3. July 1923. Pp. 305–432.—The Cultivation of Anaerobes in Auto-digest of Pancreas, by F. P. G. de Smidt. A medium made by incubating minced pancreas with chloroform for 24 hours gives free growth of anaerobes and other organisms and has a high concentration of amino-acids. Quantitative measurements of the relation of growth to reaction are given.—On Catalase in Bacteria and its Relation to Anaerobiosis, by A. B. Callow. Aerobes (except streptococci) have considerable amounts of catalase, anaerobes none. It is therefore possible that anaerobes fail to grow in the presence of oxygen because they are killed by the hydrogen peroxide which is then produced and not destroyed by catalase.—Bacterial Catalase, Anaerobes, and Oxygen, by J. W. McLeod and J. Gordon. In two papers the authors give much further information about the presence of catalase in and the production of hydrogen peroxide by a number of bacteria and suggest a classification based on these properties. In the presence of oxygen anaerobes produce hydrogen peroxide to which they are very sensitive. Ordinary media exposed to light are unsuitable for the growth of anaerobes and other organisms which are sensitive to peroxides owing to the development of traces of these substances in the medium.—Observations on Granules of Nucleolar Origin found in the Cells of Malignant Neoplasms during Mitosis, by H. A. Haig.—The Complement-fixation Test in Tuberculosis, by H. L. Coulthard. A thorough investigation of the various preparations of tubercle bacilli which have been used in the complement-fixation test leads the author to prefer simple suspensions of killed bacilli in saline. The reaction is highly specific, but is given by not more than 80 per cent. of cases of pulmonary tuberculosis and 50 per cent. of other forms. Acute infections generally give negative results and the strongest reactions are given by cases of chronic phthisis which are doing well; cases which are failing become weak or negative. The reaction therefore may be of some prognostic value.—The Glands of Internal Secretion in Experimental Avian Beri-beri, by V. Korenchevsky. Deprivation of vitamin B leads to hypertrophy of the adrenals, atrophy of the thymus, and atrophy of the splenic pulp; less constantly to activity of the thyroid, hypertrophy of the interstitial cells of the testis, and increase of the light cells of the pituitary.—The Influence of the Mother's Diet during Pregnancy and Lactation on the Growth, General Nourishment, and Skeleton of Young Rats, by V. Korenchevsky and M. Carr. Proper supplies of fat-soluble vitamin and calcium to the mother during pregnancy and lactation are most important for the welfare of the young.—Heteromorphosis (Metaplasia) of the Alimentary Tract, by G. W. Nicholson. The author describes gastric mucous membrane in a persistent vitelline duct, in Meckel's diverticulum, in a cyst of the pancreas, in inflamed gall-bladders, and in a tuberculous ulcer of colon. He points out that these abnormalities support an epigenetic mechanism of development and differentiation—i.e., environment determines which of the many potencies of cells shall be dominant.—Titration of Complement in the Wassermann Reaction, by F. C. Lewis. More delicate results are obtained by a finer gradation of quantities of complement than is generally used.—Bordet's Extract in the Wassermann Reaction, by H. D. Wright. Works as well as the more usual preparations, is stable and convenient.—A New Method of Decalcification, by C. Powell White. A solution of ammonium citrate, neutral or even alkaline, has no harmful effect on the tissues and leaves the staining unaffected.—Method of Mounting Museum Specimens, by G. S. Williamson and I. H. Pearse. Labels on thin celluloid mounted in gelatin.—" Minute Bodies " in Two Cases of Epidemic Encephalitis, by C. Da Fano. A further account of the occurrence of the stainable particles, possibly parasites, previously described by the author. —Pneumococcal Endocarditis in Rabbits, by W. Mair.—The Effect of the Individual Host on the Virulence of Pneumococci, by C. H. Browning and R. Gulbrausen.—On *Bacillus coli anaerogenes*, by D. Nabarro. An account of the occurrence, variation, and serological reactions of a number of non-gas-forming strains.—The Origin of the Mononuclear Phagocytes of the Lung, by D. F. Cappell. The phagocytic cells of the alveoli are at first derived from special areas of the alveolar epithelium and in the later stages of irritation from the endothelial cells in the alveolar walls.—Modification of Victoria Blue Method of Auglade and Morel for Neuroglia Fibres in Frozen Sections, by J. Anderson.—An excellent photogravure of the late Prof. James Ritchie, for many years secretary of the Pathological Society and editor of the journal, is issued with the present number.

New Inventions.

A NEW URETHROSCOPE AND ITS USE AS A VAGINOSCOPE FOR THE TREATMENT OF VULVO-VAGINITIS IN CHILDREN.

Those who prefer a light urethroscope with the lamp at the end of the cannula may be interested in a new pattern, which has the advantages that the lamp-stem cannot obstruct the field of view; the lamp-bulb is in a recess and does not shine into the observer's eye; the operating attachment is very light, easy, and precise in action, and the instrument, with electro-cautery attached, weighs less than three ounces. The cannula, D, shown in the figure, has its end bevelled, and the lamp-stem is carried in a special tube in the long side of the cannula as shown at N, the bulb being very close to the end so that it lies in a recess and shines across the field. After removal of the introducer, G, the lamp, carried on C, is passed down the side-tube, shown in cross-section at O P; and the diagnostic eye-piece, K, is fitted into C, which has on one side the electrical switch, E, and on the other the bellows attachment, F. The operative attachment, B, is very simple. It consists of an outer cylinder with a longitudinal slot in one side, up and down which the handle of the instrument, L, can travel. In order to retain the air on inflation, the slot is covered by an internal cylinder fitting the outer one very closely. This internal cylinder has a short metal tube set in it at right angles to the long axis, so that it lies within the slot in the outer cylinder. Through the metal tube is passed the handle of the instrument, the stem of which is screw-threaded, as shown on I, so that it can be screwed into the head of the handle within the instrument. The whole is made airtight by a short piece of rubber tube, one end of which grasps the instrument handle and the other the tube through which this is passed. The electro-cautery is carried in the same way as the ordinary instrument and handle, the portion H being detachable from M, so that it can be passed up the inside of the operating attachment and fitted to the portion M, which carries the terminals and switch, and is fitted into the tube mentioned above in much the same manner as the ordinary instrument. A different eye-piece, A, is employed in the operative attachment, owing to the longer focus required. I have found the electro-cautery wonderfully convenient, as it is a very simple matter to bring the end into contact with any part required and then to turn on the current by pressing the button switch shown opposite to M in the diagram. This instrument with larger cannulas—namely, 28, 30, 32, and 34 F—is being used in the V.D. department at St. Thomas's Hospital for the treatment of vulvo-vaginitis in children. Evidence proves that one reason for the failure of ordinary methods of treatment of this troublesome complaint is that under the ordinary douching and swabbing which are usually employed the medicament does not reach infecting organisms in the fornices of the vagina.



The plan of treatment adopted, which has so far given very promising results, is to pass the largest cannula, with the introducer, which the hymen will allow. The introducer is removed, the lamp attachment inserted, and the vagina inspected under air inflation, as in ordinary urethroscopy. The view of the cervix and fornices which is obtained in this way is perfect. After this the outside of the cervix and the whole surface of the upper reaches of the vagina are painted with 25 per cent. mercurochrome 220. This can be done either by passing a dressed urethroscopic stick through the cannula after removing the eye-piece, or under air inflation by using the operating attachment and a dressed probe. Whichever method is chosen, the operation is not complete until every nook and cranny has been treated, as verified by inspection under air inflation. Care is taken that the dye does not reach down as far as the vulva in such strength: it will trickle down later, but will by then have become diluted. Naturally, the urethra and other infected parts must also be treated, but the method outlined above of insuring that every part of the vagina is reached by the chosen medicament seems rational, and the results have certainly been most encouraging. So far only mercurochrome has been tried; doubtless a large array of other drugs will suggest themselves to workers in this field.

The instrument has been made for me by the Genito-Urinary Manufacturing Co., 66, Margaret-street, London, W. 1.

L. W. Harrison, D.S.O.,
St. Thomas's Hospital, S.E. Colonel, R.A.M.C. (ret.).

From the list of Birthday Honours which appeared in The Lancet of June 9th was accidentally omitted the name of Lieut.-Colonel T. R. St.-Johnston, C.M.G., who was a medical officer in Fiji for over ten years, and is now Colonial Secretary of the Leeward Islands. His " South Sea Reminiscences " were recently reviewed in our columns.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the principal health tatistics of a group of county and rural districts for 922 :—

District.	Estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
							Infant mortality		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Legit.	Illegit.	Maternal mort. in childbirth.
ertfordshire ..	334,706	17·4	10·7	0·7	1·3	2·3	52	129	4·5

ridlington R.D.	8,154	18·6	12·0	0·4	1·0	1·9	32	136	6·8

C.D. = combined district. R.D. = rural district.

Hertfordshire.

Dr. H. Hyslop Thomson states that special efforts re made to deal with all open cases of tuberculosis insanitary areas or in unhealthy or overcrowded ouses. The opening of the County Sanatorium at Vare Park, with accommodation for 130, marks an nportant stage in the council's scheme. The absence adequate accommodation for low-grade and comlicated cases of mental defect is seriously felt from me to time. The need for a few efficient small-pox ospitals to take the place of the large number of xisting small hospitals, many of which are of indifferent onstruction, is pointed out. Provision for the supply diphtheria antitoxin is only made by about half the 34 districts. The educational work of the centres" has brought about a reduction in bottleeding, and the decline in notified cases of ophthalmia eonatorum is claimed to be the result of the use of lloidal silver by the midwives.

Dr. Thomson again complains of the dumps of nported refuse. The Ministry of Health has suggested les to be observed by dumping authorities, but legistion will be needed to give the county council power enforce these rules. One improvement has been ought about by the Ministry—namely, that railway agons conveying refuse are required to be covered. he question is : Has any sanitary authority a right create a dump for offensive refuse in the district another sanitary authority, and has not sanitary ience advanced sufficiently to enable us to say that ese offensive refuse dumps are unnecessary ? The rification of our rivers has cost money but has been orth it. We think the abolition of offensive refuse umps will also be worth the cost.

Herefordshire.

Dr. Herbert Jones complains that the district councils not take the water-supply of the houses in their stricts seriously. About one-quarter of the cottage uses are supplied from sources at a distance and any dip wells which could be rendered safe are not ndered safe. It is also quite common to build a new ttage before ascertaining whether there is any suitle water-supply available. Dr. Jones has no mpathy with any occupier who complains that his il closet is a nuisance. The remedy is in his own nds—viz., to see that a supply of earth is provided d used. There is a great improvement in the sanitary arrangements of the licensed houses. A few years ago it would have been difficult to find a house where one could recommend a fisherman or tourist to stay for a week-end. Now there are many comfortable country inns with sanitary conditions equal to those in towns.

Owing to the cost of repairs, routine house inspection has been in abeyance. Dr. Jones recommends that it be resumed. Thirty-six new houses were completed during the year. The accommodation for hop-pickers has been greatly improved in those districts in which by-laws are in force. Of the six rural districts in the combined district, one does not import hop-pickers but five do. Of the five councils of the districts which need to import hop-pickers, three have adopted by-laws but two have not. Dr. Jones points out that many of the hop-growers are anxious to make the pickers comfortable and that it is unfair to them that other growers do not "toe the line." The by-laws are not exacting, and one hopes that before the next report is issued the two reluctant rural district councils will have adopted them.

West Gloucestershire.

Surg.-Captain O. W. Andrews reports that the new reservoir on Ruardean Hill, the highest point in the Forest of Dean, has been completed, and that improved machinery for deep well pumping is being established at Greenbottom and will be ready for use next summer. Further extensions proposed will, it is hoped, provide a satisfactory supply for the whole of East Dean. An unusual incident is reported in the sudden disappearance of the water in three wells supplying the residents of Plump Hill Ward, East Dean. Earthquake disturbance could apparently be excluded, and it is suggested that the occurrence is due to the driving of an adit by an iron ore company under the area affected. There is a good spring in the neighbourhood, and it is suggested that this should be used to supply a ram capable of pumping the water to a reservoir on high ground, from which the whole district can be supplied at small cost. Dr. G. F. Rigden, the medical officer of the Cinderford Mothers' Club and Babies' Welcome, referring to industrial depression, says there are not an unusually large number of cases of malnutrition, but that he has been many times struck by the evident signs of under-nourishment in the mother of a well-nourished child.

Dumfries County.

Dr. J. Maxwell Ross reports that there were 936 legitimate and 116 illegitimate births in the County Landward. The mortality is not given for legitimate and illegitimate infants separately. The total rate per 1000 births was 85, the male rate being 97 and the female 71. Dr. Ross reviews the tuberculosis scheme ; 27 shelters are available for use throughout the county. Sanatorium accommodation is very limited, especially for surgical tuberculosis cases, which need such prolonged treatment and for whom successful domiciliary treatment is impossible. The disposal of sewage by the burghs and special drainage districts is not yet satisfactory. In one case the difficulty is the cost to a village with a low rateable value. The pollution of the Nith by black water, apparently pumped from the coal-mines, and also by lead from Wanlockhead lead-mines has received attention. The question has arisen as to whether the former pollution can be dealt with under Section 5 of the Rivers Pollution Prevention Act, 1876.

Doncaster Rural.

Dr. A. B. Dunne reports marked building activity in five of the 37 parishes included in his district. The sinking of the shaft of the new colliery at Armthorpe has been actively carried on ; 472 new dwelling-houses and bungalows have been completed during the year.

Guildford Rural.

Dr. R. W. C. Pierce reports a considerable prevalence of influenza in the early part of the year and that schools had to be closed for this cause. The new slaughter-house by-laws have come into force and make provision for the humane method of slaughter. The 112 new houses completed during the year include 50 erected in Artington parish by Onslow Village, Ltd., now absorbed into the borough.

Stockton Rural.

Dr. Thomas J. Kirk reports a slight influenza epidemic in the last month of 1921 and the first month of 1922. The number of new houses completed during the year was 96, all by private enterprise.

Bridlington Rural.

Dr. William A. Wetwan reports that a few houses have been built but not enough to warrant turning out the occupants of 40 to 50 dilapidated dwellings and putting pressure on the owners of many more to bring them up to date. This is Dr. Wetwan's farewell report after 31 years' service, and he makes reference to the sanitary improvements which have taken place in the district during that period.

SCHOOL MEDICAL SERVICE.

Bristol.

LAST year 28,132 children were medically examined; 16,248 of these were routine, and 11,884 special inspections. Of the 1165 children suffering from enlarged tonsils and adenoids, 984 were recommended for treatment. 497 new cases were examined at the tuberculosis dispensary, and of these 57 were classified as definite pulmonary tuberculosis, 212 as cases of involvement of the hilar glands, &c., 20 as suspected tuberculosis, 208 as non-tuberculous. There were 295 cases of scabies, 2358 of impetigo, and 418 of ringworm of the scalp dealt with during the year; 183 of the ringworm cases were carried over from last year. Most of the 1050 cases of external eye disease occurred amongst debilitated children from the poorer homes. Attendances at school clinics during the year amounted to 172,487. A campaign was initiated in 1921 against verminous conditions. The coöperation of teachers, health visitors, infant welfare centres, schools for mothers, Sunday schools, boards of guardians was enlisted. Dr. R. A. Askins reports that a very great amount of good has resulted. He considers that if public interest can be kept stimulated in this problem we may soon see this evil reduced to such dimensions as to make its final extinction possible. Open-air classes are held in three city parks, each class accommodating 25 children. In wet weather the bandstands, protected by canvas wind-screens, are utilised, and the attendance at these classes rarely drops below 90 per cent.

Colchester.

The total number of children examined under the routine group was 2134, and 47·2 of these had defects requiring treatment or further observation; cases of uncleanliness or dental defects are not included. The number of children with defects is lower than that of the previous year, and Dr. W. F. Corfield observes that there appears to be only one reason to account for this—"the surplus of defects that had become chronic during the war and also the cases of malnutrition and debility resulting therefrom have now been overtaken, and the above figures are somewhat about a normal return." But surely the remarkable effect of the war on school statistics all over the country was the decrease in the number of cases of malnutrition and the feeding cases. The class for stammerers held last year has not yet been resumed, and the children returned to their ordinary schools. The teacher in charge of the class visited these schools and reported on the condition of the children. Of the 37 who attended the classes, two left the town and ten left school. The head teachers, with one exception, agreed as to the great improvement in speech effected by the classes, and an effort is made to keep up the practice of voice exercises. Of the 1580 children referred for treatment, 728, or less than half, actually received treatment.

At present little attempt is made to encourage parents to send or bring children to the dental clinic, as the dentist has his time fully occupied with those who come without such pressure. The medical officer suggests two methods by which this lack of interest could be stimulated: (1) the services of the dentist be secured for an extra half day a week; and (2) a dental dresser be employed to help the dentist. As it is, the dentist was employed on fewer occasions during 1922 than 1921, and we would suggest that in medical treatment of school-children, as in everything else, the demand creates the supply rather than vice versa. In this borough the demand appears to require energetic stimulating.

Swindon.

Altogether 3697 inspections were made. Of the 2673 children examined in the routine group, 45 suffered from malnutrition, 73 from defective hearing, 2 from otitis media, 55 from other ear affections, 13 from scabies, and 25 from speech defect. During the year there were 227 cases of ringworm, which has been prevalent in Swindon for many years. The work of stamping out this disease is now well in hand, and at the end of the year there were only 23 cases in an infectious condition, and every case was under treatment.

The prevalence of thyroid enlargement in Swindon led to the establishing of a clinic to deal with this affection, and Dr. Dunstan Brewer reports on the result of a year's treatment of those cases who were handicapped either by the appearance of the enlargement or by symptoms of disordered thyroid action. At first the cases were treated by simply painting the neck with tincture of iodine, and a definite improvement in these cases is recorded. On the assumption that the improvement was not due to any local action but to the absorption of iodine, a second batch of cases were painted under the armpits instead of on the neck. A more rapid improvement is recorded in such cases. A third batch was treated with iodide of potassium given internally with no apparent improvement of any description. Collosol iodine given internally proved to act better than any other treatment, and is now the standard method employed. The statement in the report that methods of treating stammering and similar defects of speech at present available in this country are of no practical utility, as they entail a cost which neither parents nor ratepayers are prepared to face, is surely inaccurate. We would refer Dr. Brewer to the six London County Council clinics for such treatment, which have been doing excellent work in this direction for the last two years, and can certainly not be called expensive.

THE PASTEURISATION OF MILK.

A REPORT BY THE MINISTRY OF HEALTH.

IN a recent report which constitutes one of the Ministry of Health series of reports on public health and medical subjects, Dr. J. M. Hamill[1] gives a brief account of the nature and object of pasteurisation, and the part which it may legitimately play in securing a safe and satisfactory milk-supply. His notes are also intended to serve as a guide to local authorities and others in respect of essential requirements in the design and construction of pasteurising appliances which should be complied with in order to satisfy the provisions of the Milk (Special Designations) Order, 1923, in regard to pasteurised milk.

Definition.

At the outset Dr. Hamill defines the object of the pasteurisation of milk as the destruction by heat of pathogenic organisms, and the reduction of the number of other organisms, especially those which cause milk to go sour, without appreciable alteration of the physical and chemical characters of the milk. When milk is heated to a relatively high temperature such, for instance, as 175° F. to 212° F. pathogenic organisms may or may not be destroyed, according to the actual temperature attained and the duration of exposure of the milk to it ; in any case the physical and chemical properties of the milk undergo considerable alteration as a result of such treatment, and from a commercial point of view the quality and saleability of the milk is impaired. It is also possible that from a nutritive point of view such milk is less desirable than milk not so treated. Experience has shown that exposure of milk to a temperature between 145° F. and 150° F. for 30 minutes, if carried out with due attention to detail, destroys virtually any pathogenic organisms present in the milk without producing appreciable change in its physical and chemical characters. From the public health point of view, therefore, where milk is concerned, the term " pasteurisation " should be confined to the process of heating to not less than 145° F. and not more than 150° F. for a period of 30 minutes. Dr. Hamill uses the term strictly in this sense.

---

[1] Reports on Public Health and Medical Subjects. No. 17: Notes on the Pasteurisation of Milk. By J. M. Hamill, M.D., D.Sc., Medical Officer of the Ministry of Health. 1923. 2*d.*

Effect of Pasteurisation on Bacterial Content of Milk and on its Chemical and Physical Characters.

Amongst the pathogenic organisms with which milk may be accidentally contaminated are *B. tuberculosis*, *B. diphtheriæ*, *B. dysentericus*, *B. typhosus* and other organisms of the typhoid-paratyphoid group. All the above organisms are destroyed by pasteurisation ; the virus of foot-and-mouth disease is also destroyed, and although a small proportion of tubercle bacilli may, under certain conditions, escape actual destruction, their virulence appears to be so impaired as to make them harmless. Certain strains of streptococci may also survive pasteurisation, but the streptococci believed to be responsible for septic sore throat are destroyed by the process. Pasteurisation, therefore, renders milk reasonably safe as regards risk of transmitting disease. But apart from pathogenic bacteria milk always contains a number of non-pathogenic bacteria which gain access from the hands of milkers, from particles of manure, from dust and dirty utensils, etc. The number of these bacteria, quite apart from their pathogenicity, indicates the care bestowed upon its production and handling. Dirty milk is, of course, more likely to contain pathogenic bacteria. A proportion of the non-pathogenic bacteria are sporing organisms ; amongst them are lactic acid bacteria which produce lactic acid during their growth and cause the souring of milk.

Pasteurisation does not destroy the whole of the non-pathogenic organisms in milk, but may reduce their number by as much as 99 per cent. As a general rule it may be said that the number of bacteria after pasteurisation is greater in milk which contained a large number of bacteria before pasteurisation than in milk which originally contained relatively few bacteria. Thus the bacterial content of pasteurised milk affords an indication of the bacterial condition of the milk before pasteurisation.

When milk is properly pasteurised the majority of its chemical and physical characters show no appreciable change. The taste and flavour are hardly at all altered ; alteration in the taste of the milk may depend, to some extent at any rate, upon exposure of the milk to air at the pasteurising temperature—in other words, oxidation may play a part in the change. If this be so the desirability of avoiding so far as possible exposure of milk to air during pasteurisation is obvious. If ordinary raw milk is allowed to stand, the cream gradually rises to the top and a line of demarcation, the " cream line," appears between the cream and the remainder of the milk. In milk pasteurised at 145° F. for 30 minutes the cream line is hardly if at all affected, but above that temperature the cream rises slowly and imperfectly, and in milk pasteurised at a temperature of 148° F. the cream line may be decreased by 40 per cent. From a commercial point of view the integrity of the cream line is important, because consumers are apt to look askance at milk in which the cream line is poor. In milk pasteurised at 145° F. for 30 minutes no appreciable change takes place in the milk proteins ; if, however, the temperature is raised to 150° F. for 30 minutes a small proportion (about 5 per cent.) of the milk albumin is rendered insoluble. Coagulation by rennin occurs slightly more rapidly in pasteurised than in raw milk. The soluble calcium and magnesium phosphates of the milk do not become insoluble or separate out when milk is pasteurised at a temperature of 145° F. for 30 minutes. This treatment has, furthermore, only a slight effect upon the enzymes which are present in milk.

The effect of pasteurisation on the vitamins in milk is important. Milk is rich in fat-soluble A vitamin and also contains water-soluble B vitamin and the antiscorbutic vitamin (or C vitamin). Both fat-soluble A vitamin and water-soluble B vitamin have a relatively high resistance to heat, so that pasteurisation has practically no effect upon them. The antiscorbutic vitamin, however, is sensitive to heat above 122° F. and there seems to be little doubt that pasteurisation at 145° F. for 30 minutes weakens the antiscorbutic property of milk. The destruction of vitamins appears to be due to oxidation and is accelerated in the presence of air. Any precautions taken in pasteurisation to exclude air with the object of preventing changes in taste and flavour would also act beneficially in safeguarding the vitamins.

Some Considerations in Regard to Pasteurisation.

In general it is desirable that food should be consumed in its natural fresh condition whenever possible, but in densely populated areas the circumstances are often such that, unless perishable food like milk can have its keeping qualities improved by some process which does not appreciably alter its properties or impair its nutritive value, a proportion of the population will be forced to curtail or even do without a very important food.

An ideal milk-supply, obtained from perfectly healthy cows under the cleanest conditions and consumed immediately with the least possible manipulation or handling, is difficult of attainment. Milk of this high quality must necessarily be limited in amount and its cost precludes its use by the average consumer. As England is a highly urbanised country, much of the milk-supply has to be transported considerable distances, a circumstance unfavourable to its keeping qualities and often resulting in considerable loss of milk by souring. Pasteurisation may be regarded as a factor in the extension of the consumption of milk by urban dwellers, many of whom at the present time do not consume as much milk as they should. Pasteurised milk is, of course, just as liable to bacterial contamination as clean raw milk, and since it still contains some lactic acid producing organisms it will eventually go sour just as does clean raw milk. It is essential, therefore, that it should be thoroughly cooled immediately after pasteurisation and kept under good conditions until consumed.

It is sometimes asserted that bacteria grow faster in pasteurised than in raw milk. Experimental evidence, however, does not bear this out, but goes to show that the rate of bacterial increase is approximately the same in raw and pasteurised milk when comparison is made between milks having about the same bacterial content. It is also alleged that pasteurisation will not encourage farmers to exercise cleanliness in production of milk, and will enable dirty and stale milk, otherwise unfit for sale, to be placed on the market. But the keeping qualities of pasteurised clean milk are superior to those of dirty milk after pasteurisation. It is, of course, possible to prolong the life of pasteurised milk by repasteurisation, but this process would permit deviations from the normal to an extent which is undesirable.

It is occasionally stated that pasteurised milk does not agree with all children, but the same may be said of any milk ; extensive experience of feeding children on pasteurised milk goes to show that it is as well borne by them as raw milk, and, except in regard to antiscorbutics, it appears to be equally nutritious.

Appliances Employed in Commercial Pasteurisation.

A pasteuriser should be moderate in cost, reliable, efficient, simple, compact, durable, easily kept clean, easily operated, and, in addition, continuous in action. A large variety of appliances continuous in action have been devised for commercial pasteurisation. They can conveniently be grouped into four categories or types.

1. "*Flash*" *Pasteurisers.*—"Flash" pasteurisation is a process in which the milk is very rapidly heated to a relatively high temperature and then cooled. In one type of flash pasteuriser the milk enters a hollow vertical cylinder at its lower end and by means of a rotating device is distributed by centrifugal force in a thin film over the inner surface of the cylinder and then leaves the cylinder at its upper end. The cylinder, and therefore the milk flowing over its inner surface, is heated by a combined water and steam jacket. The apparatus is continuous in action. This type of pasteuriser has many serious disadvantages. It is very difficult to maintain a uniform temperature, and the relatively small heating area makes it necessary to raise the temperature of the heating medium considerably higher than the temperature to which it is desired to raise the milk. This means overheating of portions of the milk and alteration of its character. Again, the milk is not retained sufficiently long at the pasteurising temperature and portions of the milk may not reach that temperature. It is impossible by means of a "flash" pasteuriser to ensure the definite results aimed at in pasteurisation.

2. "*Retarders.*"—The many varieties of design in this class of pasteuriser agree in the general principle of allowing the milk to pass through an apparatus so constructed as to delay or retard the flow of the milk and thus keep it at the pasteurising temperature for a prolonged period. All retarders are continuous in action. Retardation may be effected by various devices, such as compelling the milk to take a long course through a series of tubes or through chambers fitted with baffle plates. Where it is required that milk shall be exposed to the pasteurising temperature for 30 minutes the apparatus is so designed that a volume of milk equal to the capacity of the apparatus passes through it in that time.

Retarders possess many commercial advantages—simple design, close control of temperature, &c., but for complete destruction of pathogenic organisms retarders cannot be relied upon, as no retarding system yet designed is able to prevent a portion of the entering milk from passing through in less than the prescribed time.

3. "*Holder*" *Pasteurisers.*—The term "retarder" is sometimes used to describe pasteurisers of this class. It is desirable to restrict the term "retarder," however, to appliances of the type described above. The "holder" class of pasteuriser has for its object the elimination of the defect which retarders possess of allowing a portion of the milk which passes through them to escape too soon. It is the practice commercially to classify holder pasteurisers into two groups, according to whether the milk is heated in the holder itself or before entering the holder. The underlying principle of holding all the milk at a definite temperature for a definite time is the same in both groups. The simplest form of holder is a tank in which the milk is kept or "held" at 145–150° F. for 30 minutes and then cooled. Holders of this type having a capacity of 50 to 100 gallons are made for dairymen doing a limited trade in pasteurised milk. The holder is conveniently a cylindrical tank surrounded with a water jacket into which steam can be admitted to heat the milk, and an agitator is provided in the holder to facilitate the heating of the milk. The temperature in the jacket is raised slightly above the pasteurising temperature by the admission of steam into the water, and when the milk in the tank reaches the pasteurising temperature the steam is cut off and the milk kept in the holder for 30 minutes, when it is cooled by a flow of cold water through the jacket. Alternatively, the milk may be heated before admission to the holder and cooled in a separate cooler after being held at 145–150° F. for 30 minutes. This simple type of holder is effective, but is not continuous in action; for work on a large scale continuous action is a commercial necessity, and the simplest way in which this can be attained is by using three separate holding tanks of the same capacity. Milk is held in one tank at the pasteurising temperature for 30 minutes, whilst the second tank is being filled and the third emptied. The milk in the second tank is then held for 30 minutes whilst the first tank is being emptied and the third filled; in this way a continuous cycle of filling, holding, and emptying is achieved. The use of only three tanks, however, is open to the objection that some of the milk may be held for much longer than 30 minutes, and that one hour must elapse after the commencement of work before pasteurised milk can be obtained. These drawbacks can be minimised by increasing the number of tanks and so enabling the period of filling and emptying each to be diminished.

To enable the process of pasteurisation to be adequately controlled and supervised, it is desirable that all pasteurisers should be fitted with some form of automatic time-temperature recorder, whereby the temperature of the milk during the process of pasteurisation in relation to the time taken is continuously recorded on a chart. A permanent record of this kind is of value to the milk vendor and to those in charge of administration as a check on the proper working of the pasteuriser.

4. *Pasteurisation of Milk in Bottles.*—The advantages claimed for the pasteurisation of milk in airtight stoppered bottles are that the milk cannot become contaminated after pasteurisation and before use, and that it keeps longer than milk pasteurised in bulk. An apparatus for pasteurising milk in bottles cannot be regarded as satisfactory unless it can readily comply with the following requirements. It must be possible to ensure that the milk reaches the pasteurising temperature and is not heated above this temperature (145–150° F.), and in addition, there must be practicable means for ascertaining definitely that the milk has been kept at the pasteurising temperature for 30 minutes.

As regards the first requirement, the temperature of the heating medium (usually water heated by steam) may be considerably above the pasteurising temperature, and there are obvious difficulties in making certain that the bottled milk, the temperature of which cannot be measured directly, has attained and not exceeded the pasteurising temperature. Similar considerations apply to the second requirement. It is not a simple matter to ascertain the period during which the milk has been kept at the pasteurising temperature in the case of milk in bottles, where direct temperature measurement is impossible. The matter is complicated by the period, not easily estimated, during which the temperature of the milk in the bottle lags behind that of the heating medium. In any particular apparatus this period of lag might be ascertained experimentally, and possibly an apparatus could be designed in which it would be small, but for purposes of control and supervision a method in which the period of exposure to the pasteurising temperature can only be determined indirectly is not so satisfactory as methods in which direct observation is possible. Uncertainty could be avoided by first heating the milk in bulk up to the pasteurising temperature, and then filling the bottles already heated to the same temperature and keeping them at that temperature in the pasteuriser for 30 minutes. This method would be similar in principle to that employed in the "holder" process for milk in bulk.

DONATIONS AND BEQUESTS.—The late Mrs. Fredericke Mond, of Regent's Park, London, widow of Dr. Ludwig Mond, left to all the charitable societies or institutions to which she had been an annual subscriber for at least two years before her death a legacy, free of duty, equal to the aggregate amount of her annual subscriptions for the last eight years.

THE LANCET.

LONDON: SATURDAY, AUGUST 18, 1923.

LONDON WATER.

THE Metropolitan Water Board supplies 35 gallons water a day for the use of each of nearly seven llion persons scattered over 537 square miles and counties, water which is fit not only to wash and sh, but to drink; and this immense task is rried out with such apparent ease and regularity at the Londoner, when he travels, begins to realise the first time that water may be scanty or brackish insipid or discoloured. It was only during the eat drought of 1921 that the inhabitants of the etropolis began to think seriously at all of their ter-supply, and Sir ALEXANDER HOUSTON, director water examination to the Board, in his seventeenth nual report just published,[1] endeavours to keep alive is new and wholesome interest by describing the nders of London's water-supply in language as free m technicalities as is reasonably possible. The mplete protection of London from water-borne ease is the more remarkable inasmuch as 80 per nt. of the water is drawn from two rivers which undeniably polluted. Less than 20 per cent. mes from the deep wells in Kent and in the a valley, whose water is bright, clear and arkling, and pleasant to taste, while its undoubted rdness is not prejudicial to health although prodigal the use of soap. Its reputation for purity is nost a danger, apt, as it is, to create a feeling of plicit trust, and during the drought of 1921 the ptford "twins" well fell off so greatly in quality to require chlorination. Another well, that at altham Abbey, supplies water which, although very re bacteriologically, contains iron and sulphuretted drogen, which need to be eliminated. Although ndon well water bears such a small proportion to the ole, we are reminded that it would abundantly oply a city of the size of Birmingham.

Pollution of the river water-supply is not a fixed necessarily permanent quality. The Thames used be a great salmon river, and might be so again re it not for the effluents draining into the tidal rtion. Salmon could now thrive and spawn in the er above Teddington weir, although they cannot e the ordeal of ascending the lower reaches, and upper Thames as it is possesses great powers of uperation, for the surface water is constantly being lenished by underground springs, and during the nmer months many of the existing pollutions se to reach it direct. Investigations made 15 years showed the water at Hampton to be not greatly erior to that 55 miles higher up, the difference being slight as to suggest that in spite of fresh pollutions river is not deteriorating to any progressively rked extent along its flow. Next year the total acity of the Thames storage will be doubled on the npletion of the great reservoir at Littleton. Storage one of Nature's own methods of purification, by ich not only do the solid impurities settle and ance pollutions become greatly diluted, but pathoic bacteria gradually lose their vitality and die ring the passage of water through the reservoirs. d these reservoirs are so enormous—taken together eeding Ullswater in surface—that to all intents and purposes Londoners are really drinking lake water. Economy alone has led to the chlorination of raw Thames water in the aqueduct at Staines, by which a certain amount of additional pumping is avoided, and this chlorination has been carried out without giving rise to a single complaint of taste among the two million persons who drink it.

The Lea valley supply has peculiar interest, derived as it is largely from the New River, an artificial channel nearly 30 miles in length, with its intake safely above the Hertford sewage works. This rivulet is practically free from pollutions along its whole course, but has troubles of its own, for in the spring of each year abundant growths, chiefly of diatoms, develop to such an extent as to block the filters, and while such algicidal agents as chlorine or copper sulphate have been sometimes effective in the reservoirs, no panacea has yet been discovered for the prevention of algal troubles. New River water is continuously diluted as it flows with pure well water, and its volume would suffice to supply such a town as Liverpool or Manchester. Sir ALEXANDER HOUSTON is rightly proud of the results of the water examination which he directs, but his pæan of praise for the present supply is not, as he cannily remarks, to prejudice him in calling attention now or hereafter to any imperfections which may be found in the quality of the water. With whatever care and foresight, the water expert cannot discover all the hidden dangers to which a water-supply of this magnitude may be exposed. Safety lies in not introducing any new factor into waterworks procedure until it has the hall-mark of bacteriological approval, and in safeguarding the finally purified water against the entrance of impurities. The coöperation of the public is needed to achieve the second of these objects, and such a report as the one before us should help in forming and instructing public opinion. Let every good citizen read it.

◆

THE TREATMENT OF INFECTIONS OF THE HANDS.

IT would have been difficult to select a subject of more general interest than the treatment of infections of the hand, which was discussed at the annual meeting of the British Medical Association at Portsmouth. For this reason we gave last week an unusually long report of this session of the Surgical Section. It is probably within the mark to state that five-sixths of the adult working population follow some calling for the proper performance of which the integrity of their hands is a necessity. The importance of skilful initial treatment when these infections occur can scarcely be overestimated, for although the loss of one finger in itself may not interfere seriously with a man's occupation, when such an amputation must be resorted to the inflammatory process has too frequently spread to the palm, with the result that the grip of the hand or the movements of the other fingers are seriously impaired. In some hospitals the treatment of these patients from time immemorial has been relegated to the junior staff. The outcome of this policy has been that little interest has been taken in improving therapeutic technique, and a generation of practitioners has grown up trained in methods which are now obsolete.

It was left to KANAVEL in America to reinvestigate this subject and to infuse new life into it. The results of his labour were finally embodied in a monograph which will assuredly remain a classic upon which future treatment will be based. Although much of KANAVEL's work was published more than ten years ago, his teaching has not yet reached the majority of

general practitioners, so that we still see patients who have suffered from the commonest of all hand infections, that of the pulp of the finger, crippled by an ill-chosen median incision. Either there remains a scar too sensitive to pressure for use, or deforming scar-tissue has destroyed the delicate tactile sensibility of the pulp. Early lateral incisions are just as effective in checking the infective process without these drawbacks. The unsightly nails we still see after the healing of a whitlow result from delay in removing the nail and the unnecessary incision of the matrix. When the infection has reached the tendon sheath the prognosis as regards future mobility is rather poor, for the tendon is very likely to slough or form such adhesions that it becomes immovably fixed, whilst extension to an interphalangeal joint will almost certainly lead to a stiff finger. Here early lateral incisions are essential, but though they may pass with advantage through the subcutaneous tissue along the whole length of the finger, the sheath should only be opened opposite the shafts of the phalanges, or a troublesome prolapse of the flexor tendons will occur. The after-treatment of these thecal whitlows is exceedingly difficult and an issue with good movement is the exception rather than the rule. Sir Henry Gray's recommendation that Willems's mobilisation treatment should be instituted from the first deserves attention. After the incision the patient must be encouraged, threatened, or cajoled into active movements whilst his hand remains in a bath of weak antiseptic or saline solution. Passive movements are wrong and do harm. Drainage by this method is good. Tubes, gauze, or rubber tissue drains are seldom necessary. The worst of all infections are those which travel up from the thumb or little finger to the anterior carpal sheath. The operative treatment of this condition is a major surgical procedure and should always be carried out very deliberately under general anæsthesia, with a tourniquet applied. The areas of infection must be reached by the proper anatomical route, injury to the nerves and vessels of the palm being sedulously avoided. Even with the greatest care, the infective process may spread to the fascial planes of the forearm, and the general condition of the patient be so grave that an amputation becomes the only life-saving operation.

Mr. D. P. D. Wilkie called attention to those streptococcal infections which show such a great tendency to generalisation. With a non-suppurative limited area of infection in the hand are associated a lymphangitis up the arm, an axillary adenitis, and septicæmic symptoms. Early incision is not indicated in this condition, the principles of treatment being to aid the general resistive powers of the body, encourage elimination, and locally to institute Bier's hyperæmia.

DOCTORS AND UNCERTIFIED MIDWIVES.

A case of some interest, decided earlier in the year but only lately appearing in the Law Reports, throws light on the amount of supervision which a doctor should exercise over a woman who acts as a midwife without being certificated. The Midwives Act of 1902 declares that, if a woman is not certified under the Act, she commits an offence punishable by fine if she "habitually and for gain" attends women in childbirth "otherwise than under the direction of a qualified medical practitioner." An exception is made for emergencies, but in the case to which we draw attention (Davis v. Morris, *Law Times Reports*, vol. cxxix., p. 88) there was no suggestion of an emergency. The facts were that five expectant mothers had engaged an uncertified midwife's services; qualified medical practitioners were also retained in each case, but they did not pay any professional visits until after the confinements which were attended by the woman alone. In these circumstances she was prosecuted under the section. The doctors who had been retained came and gave evidence on her behalf. They said she was in their opinion capable and trustworthy; they had given her no specific instructions; it was unnecessary to do so; she was acting, they said, under their direction in attending the confinements. The magistrates had to consider whether this was sufficient supervision under the Act, or whether "direction" did not mean special instructions suitable to the particular case. They came to the conclusion that no offence had been committed and they dismissed the prosecution. It turns out, however, that they were wrong. The Lord Chief Justice pointed out that in no case was there any professional visit by the doctor; in no case was there any professional inquiry or any specific instruction. There was thus no evidence on which the magistrates could find that there had been any direction at all. Direction must be real and not nominal. "The medical practitioner should accept more than the nominal responsibility for the case. He must make himself acquainted with the particular requirements of the patient. It is not enough that there should be a qualified figure-head in the background; the unqualified person must be acting under the real direction of a medical practitioner."

This judicial homily deals, we take it, not so much with the abstract standard of doctors' conduct as with the conditions necessary to be established in a court of law if an uncertified midwife is to be found not guilty of an offence against the Act. But as there is no statutory definition of "direction," the decision is valuable. It is only fair to add that the woman whose action was in question had formerly been a certified midwife, but her certificate had been withdrawn. In the eye of the law she may have been uncertified and unqualified, but the skill and experience which in time past had been sufficient to earn her certification were, doubtless, well known to the doctors under whom—if not under whose "direction"—she was serving.

◆

ALTERATIONS OF VIRULENCE BY PASSAGE.

It is commonly held—and on sound experimental grounds—that when a dose of many millions of bacteria is given to an animal the great majority of the organisms are soon killed and disposed of, and that fatal infection, if it occurs, is due to the survival and multiplication of the relatively infrequent individuals which are able to withstand the attempts of the animal to destroy them. If after the death of the first animal this new race of exalted virulence is inoculated into a second host a similar selection occurs, and so on through successive animals until the capacity of resisting the mammalian body, in other words the virulence, of the organism has by this selective breeding been developed to the highest possible degree. Whether the mean virulence of the race which is finally obtained is greater than that of the most virulent individual of the original inoculum is unknown, but if there is any such progress in absolute individual virulence selective breeding seems to be the basis of this pasteurian exaltation of virulence by passage. It seems likely, too, that the same process goes on during the course of a natural epidemic. Several experimental observations have, however, lately been made which indicate that this is not always the sequence of events.

Prof. C. H. Browning and Miss R. Gulbransen[1] noticed that very small doses of pneumococci, which n large quantities were rapidly fatal, might set up a chronic pneumococcal septicæmia in mice lasting at least several weeks, during which time the organisms can hardly have been engaged in selective breeding for virulence. The results in this instance may have been due to the original dose having been only a small sample of the pneumococcus population which by random sampling did not happen to contain any highly virulent individuals. If that were the explanation, the experiment would not come off every time, for some of the samples would include the most virulent cocci. The same authors[2] later pointed out that the virulence of the pneumococci present in the heart's blood of a mouse dying within 48 hours of inoculation may be actually less than those inoculated into the animal, and they have recorded a similar loss of virulence in fatal infections of mice with tubercle bacilli. Dr. W. MAIR[3] also records some very significant observations. Rabbits received a prolonged course of inoculation with dead pneumococci and their serum protected mice against many fatal doses of live organisms. The animals hen received doses of living pneumococci; after some months they deteriorated in general health, and on examination were found to have a pneumococcus septicæmia with extensive vegetations on the heart valves, reproducing broadly the picture of chronic infective endocarditis in man. The organisms isolated rom the blood proved to have lost their virulence for rabbits and mice in the sense that large doses no onger caused acute death. Dr. F. GRIFFITH[4] has also shown that these results may be reproduced in vitro. By growing pneumococci in their own immune serum he finds that a fresh race develops with different cultural characters, resistant to agglutination (as in Dr. E. W. A. WALKER'S classical experiments with typhoid bacilli[5]), impotent as antigen, and with a marked loss of virulence. These modifications suggest hat the organism has been selected into a form which to a large extent fails to interact with the host, which is "naturally" immune to it to a certain degree, and which will set up local changes only in such places as the avascular heart valves, where the normal mechanism of response and resistance is defective. It is of much interest in this connexion to recall that Sir THOMAS LEWIS and his collaborators have lately shown[6] that the incidence of chronic infective endocarditis in man is largely determined by the occurrence of small congenital valvular defects.

---

[1] Journal of Pathology and Bacteriology, 1923, xxvi., 122.

There are evidently here a series of instances where bacteria will live for a long time in the body, and may cause death, without on the one hand being destroyed by phagocytosis or other defensive mechanism, or on the other reaching an exalted virulence by a process of selective breeding. No explanation of the phenomena is obvious, but it is plain that the facts are of importance and may open up a fruitful field of nquiry. "Virulence" may be too comprehensive a term, and it is possible that it should be dissected nto capacity to cause damage in the body and capacity to resist what the body does to destroy he parasite. Such a distinction was foreshadowed by Dr. W. W. C. TOPLEY in his Goulstonian lectures of 1918 on the Spread of Bacterial Infection. The pneumococci in Dr. MAIR'S rabbits, for example, have a considerable virulence in causing a particular ort of damage and a high virulence in escaping destruction. Which suggests that "virulence" of the first kind may require qualification in respect of different sorts of lesions, a view which finds support n the tissue and species specificity of many bacteria. Our knowledge of the relations between host and parasite is derived mostly from the observation of acute infections; it may well require re-examination n respect of chronic fatal conditions, such as infective ndocarditis.

Annotations.

"Ne quid nimis."

PROF. LEONARDO BIANCHI ON OLD AGE.

Leonardo Bianchi, the great master of Italian neuropathology and psychiatry, is this year relinquishing the professorial chair at the University of Naples to the profound regret of his colleagues and students. Prof. Bianchi took for his farewell address[1] the subject of old age, perhaps in reference to the fact that his retirement was occasioned by the age limit, and it is characterised by much interesting material and apposite remarks. Life is regulated, says Prof. Bianchi, by laws of whose nature we are only partly cognisant. We do not know why certain individuals develop precociously, or why the germ of a great talent arrives at maturity only after a long time in the most diverse changes and circumstances of life—and he went on to draw an eloquent picture of old age as it might be, which we render in his own words:—

> How many men lay down their arms in life's struggle before reaching the age of 60! Without any more enthusiasm, or eagerness, or even a new thought or application, with no longer any artistic thrill, nor any ambition, not even a hymn to Life or to beautiful and generous Nature. Such men shut themselves in the spiral recesses of an inert habit. What is the reason why one man is degenerate at 60 years and another preserves his mental faculties at 85 or even 90 or more? There is no biological law which fixes the term when decadence of the mental life begins; there is nothing absolute in this matter. The absolute is found in human laws, often inspired by extraneous interests, associated with profound ignorance of the infinite resources of Nature. Meanwhile let us respect this law, our Duty. There is something which watches over individual interests, and that is Discipline. Obedience, in proportion as the social organism becomes more complex, is the greatest human virtue! Erect an altar to it and let it be your law.
>
> As for myself, as long as I have strength and energy I will dedicate to you my whole thought. We were and are all enthusiasts of youth. I might almost say by occupation. Countless times it has incited my thoughts and rendered verdant year by year my existence with spring-like fertility. Living for several decades among you I have felt year by year the reflex of your spirit in myself, with the enthusiasms and generous impulses of youthful years, the hopes wooed by severe struggles, and the anxieties of work animated by an innate yet indefinite force which rendered even joyous the privations hidden under a chaste and sometimes painful gaiety. Youth must tend to become sublimated as it pushes forwards towards maturity and old age, which give force and experience to the prosperous life of the race.
>
> Happy are they who reach without much travail or severe losses the extreme limit of life; and fortunate is the country where a lucid and cheerful longevity is not an isolated and exceptional phenomenon. And remember that the foundations of a strong old age are laid in the vernal years of life. Let me before taking leave of you give you this advice. Keep a part of your youthful energies for maturity and old age, whose activities are the right of the civilisation of the race. With all the respect due to certain researches on rejuvenation, do not delude yourselves as to the results. The rejuvenation of rats and fowls may be nothing else than a firefly for man; just as illusory as the vital sun that Brown-Séquard dreamt of as standing still in order to carry on victoriously the battle of life. The conception of Goethe will remain eternal as regards humanity, and the modern Mephistopheles, decked out by the laboratory experimenter, will in vain bring you an amorous Margherite if your vital balance results in a deficit in the years of youthful enthusiasm. Devote yourselves to the work of the community, and you will be very happy to feel yourselves even at the age of 75 useful to your country. This is my most fervid wish for you.

Prof. Bianchi cited many celebrated men whose mental vigour in old age was proverbial, such as Hobbes, Michelangelo, Kant, Verdi, and Cardarelli, and quoted the instance of Voltaire, who, two years after he had completed the tragedy "Irene," at the age of 83, wrote to a friend, a professor of philosophy, who had apprised him of his dyspeptic troubles: "Your stomach cannot be in a worse condition than my head; my little apoplectic attack at the age of 83 is quite on a par with the state of your bowels at the age of 40. Let us put my meninges and your intestines on the same dish and give them as an offering to Philosophy."

---

[1] La Riforma Medica, xxxix., July 16th, 1923.

FAMILIAL RETINO-CEREBRAL DEGENERATION.

Since this condition was first described by the late Dr. F. E. Batten in 1903 a number of cases have been recorded, both of this disease and of the allied condition of familial macular degeneration without mental defect. An important article by Dr. W. H. Nardin and Dr. R. S. Cunningham appears in the June issue of the *American Journal of Ophthalmology*. In discussing the pathogeny of their cases the authors suggest a connexion with the previously described cases of amaurotic family idiocy, generally known by the names of their first describers, Tay-Sachs. All the cases, they suggest, may belong to one progressive type, with definitely decreasing malignity in character, depending on the time of onset of the symptoms.

> "Beginning with the Tay-Sachs type of amaurotic family idiocy, which commences early at 2 to 3 years of age and progresses very rapidly to a fatal termination, we have next in regard to the severity of progression the retino-cerebral degenerative type, the symptoms appearing at the period of second dentition, and finally those cases which, beginning later in life, from the fourteenth year on, show only changes in the retina. . . . It seems possible that the etiologic agent may be the same in these three groups, and the variability of the clinical syndrome the result of the differential resistance of the tissues at different ages."

This last suggestion is of considerable interest, and is well worth bearing in mind by those who have the opportunity of seeing these cases, which are not so uncommon as was once supposed. The present paper records five cases of the retino-cerebral type occurring in one childship of nine members. The age of onset was about seven; epilepsy and progressive impairment of vision, with pigmentation of the macula and progressive mental deterioration occurred. Complete blindness and imbecility followed, terminating with death.

VOLUNTARY AND POOR-LAW HOSPITALS.

Mr. Arthur Henderson, M.P., in a recent letter to the *Manchester Guardian*, pointed out that while thousands of patients are waiting for beds to become vacant in voluntary hospitals, many beds are empty in Poor-law infirmaries, and he called attention to the "serious disorganisation" of the public health service resulting from the distinction between the two types of institution. He referred to a hospital of 15 beds which had 300 patients on its waiting list, some of whom had been waiting for nearly a year; whilst in the Poor-law infirmaries 30,000 beds are said to be unoccupied, as a rule, in the summer months. This communication naturally led to inquiries being made as to the condition of affairs in Manchester and the adjoining districts, with the following results. It appears that at the Royal Infirmary, Manchester, alone over 1200 persons are waiting for admittance, while for all the Manchester hospitals there is an aggregate waiting list of about 4000; so that in Manchester about four would-be in-patients are competing for every vacant bed in the voluntary hospitals. Naturally the question of a pooling of bed accommodation between the Poor-law infirmaries and the voluntary hospitals has been raised. The matter is, however, not so simple as it appears. Whatever the number of vacant beds in the Poor-law institutions in and around London "in the summer months," investigation shows that, so far as Manchester is concerned, beds in the Poor-law infirmaries are filled up as completely as it is considered safe. Before the war the Manchester guardians added 100 beds every two years to meet the needs of the growing population, but this increase ceased during the war. An addition of 200 beds has now been sanctioned. When the number of sick persons chargeable to the Manchester Poor-law hospitals is compared with the total number of beds available—2500—in their institutions, there is only a very small margin of vacant beds; and, moreover, there are generally on an average of from 65 to 70 paying patients in these so-called "vacant" beds. It is stated that the guardians feel that the margin of accommodation at their disposal is so small that little good could possibly accrue from any system of closer coöperation. Much the same state of affairs obtains in Sheffield, which has 775 beds in its voluntary hospitals, while the waiting list numbers nearly 3000, and, moreover, there are very few spare beds in its Poor-law infirmaries; but a promising scheme has been evolved towards the joint control of voluntary and Poor-law hospitals. A Joint Hospital Council, on which the hospitals, the corporation, the boards of guardians, the University, the trade and labour council, and other interests are represented, has been set up and is working successfully. For a year this Council has made arrangements with the Ecclesall board for the reception of patients, paying a fixed rate per patient to the board. There are no "paying patients" in the ordinary sense of the term. To raise money to finance this scheme, it is stated that already over 160,000 of the workers of Sheffield contribute to the hospital scheme a penny out of every pound they earn, and thus become contributors with a direct financial interest in the hospitals, with free treatment therein—certain wards in the Poor-law infirmary being set aside for the use of voluntary hospital patients. By this scheme over £65,000 was raised last year. Over 1700 firms of employers collect the subscriptions, and add one-third to the workers' contributions. This year it is hoped to raise £90,000. A project is on foot to obtain land and buildings for the much-needed additional hospital accommodation, so that the necessary voluntary hospital service may be obtainable to meet present requirements as well as those necessitated by the increase of population.

MISTAKEN CHEST SIGNS.

The eighth fascicle[1] of Prof. J. Schwalbe's series of monographs on "Mistakes" is devoted to the diseases of the lungs and pleuræ, and is written by Prof. Hermann Schlesinger, of Vienna. If the rest of the series is as entertaining as this volume, there can be little doubt as to the success of its sale. It might be argued that studying mistakes is beginning at the wrong end, and that if the student were carefully taught to associate signs and symptoms with the corresponding morbid conditions there would be no mistakes. By the same token it might be argued that the rising generation should be encouraged to study the blameless lives of famous saints rather than the mottled careers of notorious criminals. But human nature being what it is, we are inclined to find more entertainment as well as instruction in the mistakes of others than in advice calculated to secure colourless perfection. On the subject of asthma alone Prof. Schlesinger is prolific in warning examples. One of the most simple and instructive signs of asthma is prolonged expiration, but the absence of this sign often fails to save the physician from himself and deter him from branding his patient as asthmatic. Eosinophilia is another useful sign of asthma which is frequently not sought, with the result that simple emphysema masquerades as true asthma. Even when asthma is correctly diagnosed it is often badly treated. Iodine and atropine are two of the most favourite remedies, and prescribed with discrimination each has its sphere of usefulness. But when potassium iodide gives no relief, and only provokes increased sneezing and coughing, to continue its exhibition is merely to risk drowning the patient in his own secretions. Yet physicians are apt to continue giving potassium iodide in such cases with a perseverance worthy of a better cause. Atropine also should be abandoned when large doses have been given for some time without benefit. As for the exhibition of adrenalin, it seems to be a veritable pitfall, and when it is given in cases of "cardiac asthma" with disease of the coronary arteries it may provoke severe angina and even death. Prof. Schlesinger appeals on behalf of the asthmatic to the specialist with a passion for progressively eroding the interior of the nose with the thermo-cautery in the benign hope that clearing the nasal passages will abort attacks of asthma. Such treatment may, indeed, do good. But, according to Prof. Schlesinger there are rhinologists who find something pathological in every nose, and whose furor operativus is never to be denied when asthmatics fall into their hands. One of the many lessons of this book of errors is that the best clue to obscure chest symptoms may be found well away from the chest, and that examination of the pupils may betray the tabetic origin of a persistent cough which for years has passed muster as an expression of bronchitis. To confess one's own mistakes is usually painful, but vicarious confession is a soothing avocation, giving joy to the confessor as well as to his audience. Even when it is robbed of its edge by anonymity, it can be made entertaining enough.

ACCIDENTAL SYPHILIS IN MEDICAL MEN.

Dr. C. L. P. Trüb,[1] of the University Dermatological Hospital in Bonn, has published a monograph on syphilis as an occupational disease in medical men. This work is frankly a compilation, and the editorial comment with which it is flavoured is of such a neutral and non-committal character that the book is little more than an expanded bibliography. But as such it is very useful and it is likely to prove a valuable work of reference; the more so because of the orderly arrangement and classification of the subjects under discussion. Accidental, extragenital syphilis in medical men is, alas, quite common, and Jonathan Hutchinson alone is said to have seen more than 100 such cases. Dr. Trüb has collected 669 cases from the literature, and it is obvious that this number must represent a mere fraction of the total; syphilis is not a disease which courts publicity. The statistics concerned with the site of the primary lesion show that the fingers, hands, and arms are the parts most frequently infected, and Dr. Trüb has assembled as many as 338 cases in which the chancre was situated in these positions. In another 32 cases the eyes, and in 12 the lips, were the first structures to be infected, and only in two cases was the chancre situated in a tonsil. It is curious to note how frequently medical men and students have deliberately contracted experimental syphilis. It is, perhaps, misleading to use the term "deliberate" in connexion with medical students whose knowledge of the risks they ran must have been far too incomplete to form a basis for deliberation. The medical man who encourages the callow medical student to play the part of the experimental animal in this connexion shows a courage which is as reprehensible as it is vicarious. A separate chapter is devoted by Dr. Trüb to the problem of post-mortem infection. About 30 cases of such infection have been recorded, but only about four of them stand criticism, and even in these four cases the evidence is not as complete as it might be. Incidentally, this monograph shows very clearly how nebulous the conceptions of syphilis were up to the time of Jonathan Hutchinson; the vast literature referring to pre-Hutchinson cases of syphilis is practically valueless as judged by modern standards of diagnosis. But even though proven cases of post-mortem infection with syphilis are very rare, this risk cannot be regarded as negligible, and reference is made by Dr. Trüb to the investigations of Prof. E. Hoffmann, who addressed a questionnaire on this point to numerous pathologists and specialists in syphilis. He obtained 29 answers, and in eight of them accounts were given of more or less definite cases of post-mortem infection. One of the most interesting but most incomplete chapters is that concerned with syphilitic infection without a primary chancre. At least 16 such cases have been recorded in which the patient was a medical man, and in five of these cases the infection was extragenital and vocational.

An important question asked by Dr. Trüb is: How shall the medical man who has contracted syphilis comport himself with regard to his professional work? The answer given is quite definite. In the primary and secondary stages, and when there is a definite rash on the hands and arms, no medical man should attempt to operate or attend maternity cases. When the syphilis is in the tertiary stage, it may be sufficient to protect the limbs with rubber or plaster, but it would be well if full work were not resumed until vigorous specific treatment has been shown by the Wassermann reaction to have been successful. Even then the medical man should undergo systematic serological and clinical examination from time to time, keeping an alert eye for any signs of syphilis of the hands and arms. If the Wassermann reaction is positive, it is necessary to be careful, and, preferably, to discontinue medical practice, even when there are no symptoms. This is a hard saying, and obedience to it must often entail a self-sacrifice verging on economic ruin. But its neglect may sometimes have far-reaching consequences, and there have undoubtedly been several cases of syphilis transmitted to patients by midwives and medical men. In one instance alone a midwife has been known to infect 30 women. This case was recorded in 1883, and it is to be hoped that with our present knowledge—diagnostic and therapeutic—of syphilis, the vocational syphilis of doctors has become a much less serious matter than it was.

WORK OF THE ROCKEFELLER FOUNDATION.

IN the review for 1922[1]—including a summary for the first decade—of the work accomplished by the Rockefeller Foundation, by the President, Mr. George E. Vincent, there is presented a survey of unparalleled beneficent work. The Foundation was originally incorporated on May 14th, 1913, under a special charter by the State of New York, and with an initial endowment of $100,000,000, the gift of Mr. John D. Rockefeller. During the past ten years the Foundation has received from its founder a total of $182,704,624. Its total disbursements have amounted to $76,800,000, representing the income from year to year, and $17,500,000 appropriated from principal. In addition, it has pledged future income to the extent of $15,600,000. There is an interesting review of the growth of the science, whose progress, it is pointed out, has followed in a general way Comte's law, which asserts that every body of knowledge passes through two stages, the theological and the metaphysical, into a third, the positive or scientific. This theme is expanded into a chapter on "From Magic to Microbe," and then into an exposition of "Methods, Spirit and Scope of Modern Medicine." As to public opinion and medical progress, it is wisely remarked that unless the leaders of opinion and a substantial proportion of the adult population appreciate the aims and methods of science, science cannot attain the place it deserves or render the service of which it is capable. But in spite of all efforts and in face of evidence there are disheartening instances of an almost benighted ignorance. The remarks on vaccination are singularly appropriate at this juncture.

> "If there is one thing that has been repeatedly demonstrated to the complete satisfaction of all well-trained minds capable of dealing logically with evidence, it is that vaccination for small-pox affords an extraordinary immunity against that disease.....In the United States the disease is widely diffused; in some regions it is almost endemic. Anti-vaccination societies carry on fanatical campaigns of misrepresentation, offering misleading statistics, invoking the authority of discredited physicians, citing unverified cases, and making emotional appeals."

There are some valuable remarks on "the training of doctors," and it is pointed out that "the idea of teaching the medical student all that is known about health and disease is on the face of it absurd." A tentative list of the medical schools of all countries prepared by the Foundation shows that there are in all 445 schools, distributed geographically as follows: United States 82, British Isles 43, France 32, Russia 28, Germany 25, China 24, Italy 21, Japan 20, India 18, Spain 11, Mexico 11, Brazil 10, Canada 9, Netherlands 8, Switzerland 5, Belgium 5. Forty-four other countries support from one to four medical schools each. It is the aim of the Foundation to hasten the development of international coöperation in medical education by all available means. An account is given of what has been done for the Peking Union Medical College, and the aid afforded to European medical scientists. Much stress is laid on the training of health staffs in connexion with public health and preventive medicine, and the manner in which this is carried out. Significant and instructive are the titles of other chapters—"Closing in on Yellow Fever," "Controlling Malaria at Low Cost," "Hookworm Disease as an Educator." We have travelled a long way since the first European conference to consider health problems—representing 12 nations—was held in 1851. In the field of international hygiene there has been established a recent creation under the League of Nations of a health organisation which has the support of 52 nations and the sympathetic coöperation of the United States. The Foundation also works through non-governmental organisations and voluntary institutions of various kinds in order to carry out its chartered purpose, which is to promote, not the exclusive prosperity of any one nation, but "the well-being of mankind throughout the world."

THE FIGHT AGAINST RABIES IN DOGS.

THE importance of the strictest observance of the regulations in force with regard to rabies in dogs can hardly be overestimated. Whereas in this island country the number of infections have been reduced to a vanishing point, on the Continent, owing largely to laxity during the war and post-war periods, the disease is greatly on the increase. Recent figures collected in Vienna[1] show that the number of infected dogs trebled during the years 1919–22, and that during the same period the number of human beings treated at the Lyssa Institute doubled. The number of dogs registered in Vienna rose in those years from 37,000 to 77,700, so that in 1922 there was roughly 1 dog to every 24 inhabitants, children included, and this number does not account for the many unregistered dogs. The effect of legislation in the directions of a dog tax, compulsory muzzling, immediate notification and destruction of all dogs known to be or suspected of being infected, regular periodic examination of all dogs and notification of all dog-bitten humans, has been remarkable, as figures from many countries show. The experience gained during the last 40 years at all treatment centres teaches that if these measures were systematically and conscientiously carried out, the disease might be completely wiped out; but it has been found extremely difficult to insist on such measures even in the large towns, and still more so in the outlying districts. One factor that has to be reckoned with is the human love of dogs, and this presents one of the greatest difficulties. Education of the public is one of the most important factors in dealing successfully with the problem. Legislative measures will take a long time to free mankind from the scourge, and therefore additional measures might well be adopted. Dr. Schnürer has since 1905 been employing prophylactic inoculation of dogs against the disease, a measure first suggested by Pasteur, and later worked out by Bouley (1884) and Högyes (1889), but the difficulty in applying it on a large scale to all dogs lay in the fact that to produce sufficient attenuated virus (fixed virus) not all the rabbits in Australia would suffice, and therefore Dr. Schnürer has worked out a scheme whereby stronger and more virulent doses are given, so that fewer injections are necessary, reducing the number from 14 to 2–3. According to the present experience at the Lyssa Institute, the duration and effectiveness of the protection afforded by inoculation depends on the quantity of the fixed virus introduced. As the result of experiments on 93 dogs it was found that by giving 1–2 doses containing a total of 0·33–20·0 g. of the virus subcutaneously or intraperitoneally, the animals could be immunised against infection introduced intraocularly, subdurally, or intramuscularly with 63·6–100 per cent. successes, depending on the nature of the virus and the site of introduction of the infection. Such doses were not injurious to the animals, and the immunity commences on the thirteenth to eighteenth day and lasts up to five years. To demonstrate the use of prophylactic inoculation Dr. Schnürer is now engaged in carrying out experiments on privately owned dogs, who attend as out-patients. He inoculated 50 with five injections of virus in increasing doses, giving a total of 0·665 g. The next 90 dogs were given four injections containing 0·76 g. altogether. One of these was previously bitten by an infected dog and died of rabies; in the rest up to date there has been no evidence of the disease. Fuller details and tables of results are given in the original article.

THE PRODUCTION OF CLEAN MILK.

WHILE official machinery for encouraging the production of clean milk is grinding slowly, and let us hope surely, towards its appointed end, there are abundant indications of a keen desire within the dairy trade itself, and in a variety of bodies associated with the trade, for an improvement in the purity of the milk-supply. We have before us a pamphlet on "Milk Competitions," by the National Clean Milk Society, a body whose avowed object is "to raise the hygienic standard of milk and milk products, and to educate the public as to the importance of a clean and wholesome milk-supply." The pamphlet gives a lucid and useful description of methods of improving the production and the quality of milk through the stimulus afforded by competitions. Two score card systems are described, the more elaborate adapted for assessing the efficiency of production, and the simpler system for evaluating the quality and purity of the final product. The information is set out in simple style. It is suggested that the promoters of such competitions might arrange for the prizes to be offered either by public health authorities, by local organisations anxious to promote improvement in the hygienic quality and chemical composition of the milk-supply, or by firms directly interested in the milk industry. In the same connexion reference may be made to a paper by Mr. A. T. R. Mattick, of the National Institute for Research in Dairying, Reading, on the production of clean milk. The paper deals in detail, in the clearest way, with the whole course of production of milk, from the cowshed and the milking shed to the milk room up to the stage of bottling, including details of the preparation of utensils, of premises, and of the cow. The pamphlet does not aim at putting forward any specially original views, but it succeeds in providing a simple and systematic description of procedure which should be of real value to the dairy farmer. The distribution of instructions of this type throughout the dairy industry—especially if such distribution were organised by the industry itself—would be more likely to create an atmosphere leading to improvement in milk-supply than the most heroic efforts of the official administrator. The process of cleaning must indubitably, if it is to be effective, come from within the dairy trade itself.

INTERNATIONAL CONFERENCE ON LEPROSY.

THE Third International Conference on Leprosy assembled at Strasbourg from July 28th to 31st. Official delegates representing 46 countries attended this conference, and a number of learned societies and other organisations from different countries were also represented. Great Britain, India, Australia, and some other British dominions, colonies, and protectorates were separately represented by official delegates. The conference was opened by Mr. Paul Strauss, the French Minister of Health, and the scientific sessions were held under the presidency of Dr. Ed. Jeanselme, professor of medicine in the University of Paris. The official text of the resolutions embodying the conclusions arrived at as the result of the deliberations of the conference is as follows:

---

[1] Prof. Josef Schnürer, Wiener klin. Wochensch., July 12th, 1923.

La 3ème Conférence Internationale Scientifique de la lèpre maintient les principes d'organisation de la lutte contre la lèpre admis par les conférences précédentes et adopte les résolutions suivantes :

(1) Les prescriptions legislatives concernant la lutte contre la lèpre doivent différer suivant les pays auxquels elles s'appliquent, mais, dans tous les cas, il faut interdire l'entrée des lépreux étrangers.

(2) Dans les pays où la lèpre est peu répandue, l'isolement dans un hôpital, ou à domicile si celui-ci est possible, est recommandé, tel qu'il est pratiqué en Norvège.

(3) Dans les foyers d'endémie lépreuse, l'isolement est nécessaire. (*a*) Cet isolement doit être humanitaire et laisser le lépreux à proximité de sa famille, si cette mesure est compatible avec un traitement efficace. (*b*) S'il s'agit d'indigents, de nomades ou de vagabonds et d'une façon générale de personnes qui ne peuvent être isolées à domicile, l'isolement sera pratiqué et le traitement le plus efficace sera appliqué dans un hôpital, un sanatorium ou une colonie agricole suivant les cas et les pays. (*c*) Il est recommandable de séparer de leurs parents les enfants de lépreux dès leur naissance et de les maintenir en observation.

(4) Les membres de la famille du lépreux doivent être soumis à des examens périodiques.

(5) Il faut faire savoir aux populations que la lèpre est une maladie contagieuse.

(6) Il y a à interdire aux lépreux les métiers qui les exposent à propager les germes de leur infection, mais en ce cas la société a le devoir de considérer que cette interdiction lui impose l'obligation d'assister le malade et les personnes dont il est le soutien.

As no official English text of these resolutions was presented or discussed at the conference, it would obviously be out of place to print an unauthorised translation of them.

DECAPSULATION OF THE KIDNEY IN ECLAMPSIA.

Dr. Albert Niedermeyer,[1] of Schönberg, reports a case of severe eclampsia with coma, in which the life of the patient was saved by decapsulation of the kidney.

On Jan. 9th, 1923, the patient, a primipara, aged 20, was seized with eclamptic convulsions, which rapidly increased in severity and frequency until they were almost continuous. The presentation was normal, and the membranes were intact, but the fœtal pulse-rate rose rapidly and was soon imperceptible. Catheterisation produced a few drops of brownish urine, which solidified on boiling. As the condition was urgent, and there was little possibility of saving the child (seventh month) perforation was undertaken under light chloroform anæsthesia, and the uterus was emptied. Treatment by venesection, morphia, and chloral in a darkened room was given, but the hope that the rapid emptying of the uterus would arrest the convulsions was not realised. On Jan. 10th, at 10 A.M., saline was given, one litre rectally and one litre subcutaneously, and at 11 A.M. venesection was repeated. During the afternoon coma set in with loud snoring, cyanosis, and foaming at the mouth; at 3 P.M. the saline infusion was repeated, but the coma deepened and was accompanied by complete anuria. A few drops of urine which were withdrawn coagulated. The respiration and pulse became worse, the face and lips were blue, the pupils dilated and fixed, the face sunken, and there was a tracheal rattle. As death seemed imminent decapsulation was undertaken as a last resort. At 5 P.M. the kidney was exposed under light chloroform anæsthesia, and without displacing the organ the capsule was removed as far as possible, the remainder being stripped back as far as the hilum. The wound was closed in layers and a gauze strip inserted into the lower angle. From the time of the operation onwards there were no further convulsions, the respirations and pulse improved, and the coma lessened into a quiet sleep, with disappearance of the cyanosis. On the following day, at 6 A.M., the patient reacted when spoken to, and at 9 A.M. 300 c.cm. of light-coloured urine were withdrawn on catheterisation; albumin by Esbach ½ per thousand. In the evening 200 c.cm. were withdrawn with a trace of albumin, and during the night a quantity of urine was passed spontaneously. On Jan. 12th consciousness returned, and from the next day the urine remained free from albumin. The wound healed by first intention, and on the 27th the patient was discharged.

In this case it can hardly be doubted that the operation was directly responsible for the immediate improvement. Dr. Niedermeyer is of the opinion that had it not been so, the condition of the patient was so grave, that an intervention of that magnitude must have been fatal. Of interest is the rapidity with which the operation had effect. Dr. Niedermeyer quotes Edebohl, who holds the view that decapsulation first shows its effect 10 days after the operation; but from the experience derived from the case reported, he cannot agree with him. It was obvious that here the effect was immediate, but he is inclined to think that the operation should only be undertaken in cases of acute anuria, and that in such cases it can have no purpose unless the effect is immediate. In discussing the mechanism of the results of decapsulation, he reminds us of the view expressed by Edebohl and others that new blood-vessels are formed between the surface of the kidney and the surrounding fat capsule, and thus the blood-supply to the organ is improved. But it has been shown that in some cases a new fibrous capsule very soon develops in place of the one removed, possibly before the new capillaries have had time to form, and anyway, if a new capsule did not grow, the development of the new blood-supply would be too late in acute cases, where the effect is required immediately. Most recent authors take the view that the chief effect lies in the mechanical relief of the renal tension, and the French writer Pousson, speaks of "glaucoma of the kidney." It appears that in acute anuria it is the enormous rise of intrarenal pressure, increased by the non-elastic, firm capsule, that leads to obstruction to the circulation and to the outflow of urine, and finally, to complete paralysis of the secreting cells. If this explanation is accepted, it is obvious that if decapsulation helps the kidney, it does so immediately, and it also explains why in chronic cases the results are so disappointing. It also explains why unilateral decapsulation is sufficient, for no sooner is the pressure on one side relieved, and the passage of urine accomplished, than is the attempt at secretion by the other lightened, and so the vicious circle is broken. The second kidney then gradually recovers its equilibrium. Obviously the danger of a unilateral operation is less than a bilateral, especially as the operation is hardly to be recommended except when other measures have failed and the patient is in extremis.

THE MIDDLE WAY IN THE TREATMENT OF FUNCTIONAL NERVE DISORDERS.

Dr. R. G. Macdonald Ladell, in the *Practitioner* for August, presents certain principles which have emerged from the chaos of controversy. His "middle way" lies between psycho-analytical technique on the one hand, and the total neglect of mental processes on the other. There can be but few practitioners, he judges, whose work brings them much in contact with nervous disorders who do not realise the fundamental truths of Freud's doctrines; yet, though for some cases psycho-analysis is necessary, current conflicts predominate in most of the patients who seek the aid of the physician, and for these no deep analysis is needed. But the physician must be prepared to discuss many questions, both in regard to sex and to other difficulties, when the shoe of civilisation pinches, and he must be free of embarrassment or diffidence, which, if shown by him, will only increase the patient's repressions. Plainly, as Dr. Ladell says, the personal factor is bound to count largely when dealing with these cases, and his remarks suggest that radical differences of opinion on what should be matters of observation perhaps have their origin in the temperament of the observers. We can imagine the neurotic, who is often sensitive and over-scrupulous, withdrawing into the protective shell of reticence at the slightest hint of surprise or embarrassment on the part of the physician, just as we can imagine—or perhaps recall—physicians whose manner invites that open confession which is good for the soul. One temperamental type of medical man finds himself making observations and gathering facts about neurotic illnesses which for another type remain as in a closed book. The fundamentals of psychopathology are now sufficiently established for such inequalities to be lessened by giving instruction in the subject to the medical men and women of the future. Whatever kind of case may be allotted to the psycho-therapist, the middle way in treatment must be the way of the general practitioner.

---

[1] Deutsche medizinische Wochenschrift, June 8th, 1923.

PROF. IVAN PAVLOV IN LONDON.

At the conclusion of a two-months tour in France and the United States, Prof. Ivan Pavlov of Petrograd attended the International Congress of Physiology at Edinburgh, after which he spent a week in London before returning to Russia. We have received from a correspondent an account of a visit which he paid to the Middlesex Hospital on August 6th, when he was received by a number of members of the medical staff of the hospital and its medical school, and expressed appreciation of all that he saw, being particularly interested in the cases of diabetes under treatment with insulin, and in the new laboratories which are shortly to be opened. The eminent physiologist, who is now in his seventy-fourth year, is a striking example of the boundless activity and imaginative force which is the gift of the greatest scientists. Amidst the tragic chaos of the revolution in Russia he has been able to continue his work, and it comes as a surprise to many in this country to learn that at the present moment he has some 30 fully-qualified assistants working under him at his laboratories at Petrograd. Prof. Pavlov, during his visit to the Middlesex Hospital, made especial comment on two things. The first was that the hospital, the research departments, and the medical school formed a complete unit, allowing the fullest coördination between teaching, research, and modern treatment, a condition of affairs seldom successfully realised elsewhere. But side by side with this he was disappointed to find here, as in other institutions in England, that research is seriously hampered by the severity of the restrictions on vivisection. The wide repute of Pavlov's book on the "Work of the Digestive Glands" may have obscured the realisation in the minds of the medical profession of the fact that his work has chiefly been concerned with the physiology of the central nervous system. For many years past his experiments have been directed to elucidate the problems of sleep, inhibition, and conditional reflexes. We are happy to learn that this work is now far advanced, and that Prof. Pavlov hopes in the autumn to bring out a book which will be to the neurologist as profoundly interesting and important as was his work on digestion to the general physician and physiologist.

King's College Hospital.—An extraordinary meeting of the Committee of Management of King's College Hospital was held on August 9th to authorise the establishment of a dental school under the direction of Dr. Alexander Livingston of Liverpool University. At the same meeting was received the resignation of Mr. F. F. Burghard, senior surgeon, to whose work in connexion with the hospital and medical school a tribute was paid by the chairman, Viscount Hambleden. He is succeeded on the committee as senior surgeon by Sir G. Lenthal Cheatle. To the committee was also added Mr. P. A. Willson. The other business included the appointment of Mr. H. J. R. Surrage as an additional honorary anæsthetist. The committee passed a resolution of thanks to the Winter Distress League for undertaking a considerable amount of cleaning in different parts of the hospital which could not otherwise have been done owing to lack of funds, and also gratefully accepted the offer of the Talfourd College for Girls to maintain a cot in the children's ward.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXXIII.

TREATMENT OF SYPHILIS IN THE WOMAN OF CHILD-BEARING AGE.

Some competent observers have stated that syphilis in women is in the main a much less serious infection than it is in the male. This may be so for the individual, though I am not prepared wholly to admit it; but for the ultimate welfare of the race no case of syphilis in a woman can possibly be dismissed as a light case, or as necessitating a lower standard of treatment than one showing more serious manifestations. The treatment of syphilis in women presents two different aspects: the first is that of acquired syphilis with signs and symptoms as in the male; the second is conceptional syphilis in which frequently during the child-bearing period no signs appear, the woman complains of no disability, but gives birth to premature, stillborn, or weakly and diseased children.

Acquired Syphilis in Primary or Secondary Stage.

Here the treatment is straightforward, its duration depending on the stage at which the case is seen; the patient requires a minimum of two years' steady treatment if seen in the primary stage—considerably more if not seen till secondary lesions are present.

If properly prepared—i.e., with bowel empty and no meal having recently been taken—women almost always take intravenous injections of 914 preparations well. At the menstrual period a smaller dose may well be given, but otherwise doses ranging from 0·3 to 0·6 g. are injected once a week, either of novarsenobillon, sulfarsenol, or stabilarsan, till 4 g. in all have been given. At the same time pil. Hutchinson should be taken thrice daily and a gargle of pot. chlor is used as routine after each meal. In my experience women much prefer taking pil. Hutch. orally rather than have the routine injection of Lambkin's cream in addition to the 914 injection. After a course of 914, pills are stopped for two weeks, and then a Wassermann test is done. If the W.R. is negative and the case was first seen in the primary stage, the patient is allowed to carry on with pills alone for two months when the W.R. is again tested; but if the case was first seen only when well-established secondary lesions had developed, the patient is given pills to last a month and told that a further set of injections will be given at the end of that time. The patient either takes a little sulphur at night during this month—many patients like confection of sulphur or trochisci sulphuris as aperients—or else the second course of injections is ushered in by an injection of intramine, sulphur being used as an antidote to, or as a preventive of metallic poisoning by arsenic or mercury. The second course of injections may be of a slightly different type from the first—i.e., if N.A.B. was given in the first instance, sulfarsenol (0·36 to 0·6 g. dose may be given, or silver salvarsan (0·1 to 0·3 g. dose till 1·5 g. of the latter or 4 g. of the former have been given. The W.R. is then repeated, and if it is negative and if no signs or symptoms are present the patient is treated by pills only. The urine is tested for albumin as routine before each injection and inquiry is made as to any unpleasant symptom following the last injection—any complaint of headache, sickness or urticaria requiring careful investigation. Bowels should be carefully regulated with salines and all carious teeth must be removed.

During the remainder of the treatment Wassermann tests are taken about every three months and a further course of injections is given if required. If all the tests are negative and the patient's condition is satisfactory pills only are given during the remainder of the time.

Standard of Cure in Women.

The standard of cure adopted at my clinic is persistently negative W.R. over two years without sign or symptom, even after a provocative injection has been given. If this standard is met by a patient she is discharged, on the clear understanding that if she becomes pregnant she must return for treatment by the time she is eight weeks pregnant. A case first seen in the late secondary stage is hardly likely to reach this standard of cure, and in many cases these patients after three years steady treatment are sent away and told to return twice a year for a month's ntensive treatment—i.e., injections of 914 and a mixture of potassium iodide and mercury. This method of dealing with intractable cases has so far given most gratifying clinical results.

Conceptional Syphilis.

A considerable number of women are met with who have given birth to stillborn or diseased children without themselves showing any signs of acquired syphilis, at least during the child-bearing period. These are mainly the wives of men who have had syphilis and have been insufficiently treated. These cases are most intriguing and sometimes very difficult to diagnose as they are frequently seen for the first ime during pregnancy, having been referred for an opinion from a maternity centre. When besides a history of ante-natal and neo-natal deaths a positive W.R. is obtained, treatment is at once instituted; but the W.R. is very uncertain during pregnancy and ust after delivery, so that a negative W.R. does not of necessity exclude conceptional syphilis. In such a case an effort is made to get an interview with the husband and often a very old history of syphilis is obtained, the man frequently having forgotten about t as he has had no symptoms and has not connected his wife's obstetric calamities with his old disease. I could quote instances of this type of case in which the woman's W.R. had never been positive.

It is held by some syphilologists still that a mother with no symptoms and a negative W.R. is not herself syphilitic and does not require treatment. This seems to me an unsound theory; there appears to be n these cases of conceptional syphilis a degree of mmunity in the mother herself which frees her from signs and symptoms of syphilis *during the child-bearing period;* but after the menopause symptoms frequently appear. There are in my department several women past the menopause who never had syphilitic manifestations while childbearing, and now have gummata of the back or thigh or the common ulceraion of the outer side of the ankle and a positive W.R. n practically every history a case is obtained of stillbirths or of delicate weakly children who died young; one woman, who was perfectly well till a gumma occurred on her thigh this year, has her youngest child, aged 19 years, being attended at an eye hospital for "Hutchinson's salmon patches." I think this post-menopausal appearance of symptoms is a complete refutation of the claim that these women are not syphilitic.

Treatment of Syphilis During Pregnancy.

The treatment of syphilis in women during pregnancy is practically the same as at other times. These cases of conceptional syphilis are at once given oil. Hutchinson and have a weekly injection of 914 for about six weeks; after that a fortnightly one till 4 g. has been given. Injections may be given right up till the day of delivery without ill-effect. Patients are encouraged to return as soon after delivery as possible and are then given from 6 to 10 fortnightly injections of 914 while suckling. Cases that have previously had omplete treatment for syphilis require, of course, only a few injections during pregnancy, an injection every hree or four weeks usually being ample. There has been practically no toxæmia in these cases and the hildren are remarkably satisfactory, strong, without esions, and in most cases above the average birth weight. One little known but quite definite symptom present in some of these cases of conceptional syphilis is a purulent vaginal discharge which may be slight or profuse, *is not gonococcal*, and clears up without any local treatment when antisyphilitic measures are adopted. This symptom has to my knowledge been mentioned in this country by only one other observer, Prof. W. C. Swayne,[1] of Bristol, but has been seen by me for some years and pointed out to students.

Conclusion.

I would emphasise the necessity for all practitioners to have their cases of possible conceptional syphilis carefully investigated. With a history of stillborn or weakly children and with no toxæmia of pregnancy or obvious disease of either parent the possibility of conceptional syphilis must be borne in mind; the results of treatment far outweigh any slight inconvenience—they are really brilliant; the technique is simple and the cost very moderate.

FACTORY INSPECTION IN 1922.

REPORT OF THE CHIEF INSPECTOR.

The report of the Chief Inspector of Factories[2] shows how the work of his department is becoming more and more technical and specialised; thus while there are 137,858 registered factories (apart from 145,684 workshops which for the most part are small and of inconsiderable importance), special codes of regulations, in addition to the main provisions of the Factory Acts, apply to 99,332 works or departments within works. The duty of enforcing the requirements of these codes calls for technical knowledge and must be onerous. Accident prevention has continued to receive special attention, and important progress is reported in improving the standard of safeguards; but the spirit of safety-first—the appeal to the mentality of the worker—is being called upon to effect better results. Instances of its value are quoted: a fall from a figure of 94 in 1920 to one of 52 in 1922, combined with a lessened severity rate from 1·44 days lost per 1000 workers to 0·88; a reduction in lost-time accidents from 347 in 1919 to 80 in 1922; a reduction in compensation paid per £100 wages from 5*s.* 6½*d.* in 1914 to 2*s.* 10*d.* in 1922. Such instances are proof of the value of eliminating hazardous practices. Accidents are frequent among casual labour, but far less so among regular and experienced workers; hence labour turnover should be minimised. Hours of work would appear to have been permanently reduced without recourse to legislation, and now rule at from 44–48 per week. Output would not seem to have materially suffered, while overtime rates militate against any extension in the future; the half-time system for children has disappeared even in Lancashire; the two-shift system has not had a fair trial yet, as, although 235 Orders have been made permitting it, it has, owing to trade depression, been actually used in only few cases.

Voluntary (in contra-distinction to statutory) welfare is holding its own, it is the direct outcome of the war period and is the spirit of true welfare, which must come from within—from the workers themselves and the management. In one interesting scheme the vicar of the parish acts successfully as welfare supervisor, even seeing after the fencing of machinery. Another venture is the combination of employers to support schemes for all their employees. Statutory welfare is enforced by special orders, of which there are now many applying to different industries; good work is being done thereby, but there is danger lest the letter, rather than the spirit, is complied with. First-aid equipment is now an integral part of works organisation, and septic poisoning is being materially reduced thereby, a decrease of 50 per cent. being reported by one insurance company.

Lead Poisoning.—Electric Shock.

Dr. T. M. Legge's report is rather shorter than usual; he tells of the control maintained over lead poisoning, which now only accounts for less than 250 cases a year, whereas ten years ago 500 cases seemed to be an irreducible minimum; the pottery industry still contributes unduly to the total. Interesting figures are given of the occurrence of epitheliomatous ulceration; 64 per cent. of the cases were between 40 and 60 years of age, and 20 per cent. over 60; 51 per cent. had been employed 20 years and over with exposure to pitch, tar, or paraffin; the face and neck were implicated in 43 per cent. of the cases, and the scrotum and groin in 29 per cent. The examination by certifying surgeons of young persons for fitness is gradually increasing in importance, but remains unsatisfactory for lack of any subsequent examination; about 2 per cent. of juveniles were rejected as unfit.

Mr. G. S. Ram deals with accidents due to electric shock, and again stressed the need for prolonged artificial respiration in every case; he instances cases brought round after 15, 20, 30, and 45 minutes, as well as others where efforts were either not attempted or given up after a few minutes. He puts forward an observation, quaint and unexpected, that after severe and prolonged shock, if the patient has a bad fall but escapes from fatal injuries, he recovers from the shock; and asks whether mechanical shock may not be a successful form of treatment for cardiac fibrillation, and how it should be applied.

Special Research Work.

A feature of the report is the inclusion of special research work; that of Dr. G. L. Middleton on the effects of dust inhalation will be referred to in connexion with a special report by the same author in collaboration with Dr. E. L. Macklin; another report, by E. M. Hewitt and E. M. Bedale, concerns the physiological cost to women of different methods of weight-carrying. This is an instance of laboratory research directed to elucidate a practical problem; different weights were carried (*a*) on a tray, (*b*) on a tray with shoulder strap, (*c*) with load divided, and (*d*) with load on shoulder, while the oxygen consumption per horizontal kilogrammetre of work was estimated. For loads of 20 to 30 lb. the method of carrying seemed to be a matter of personal choice; at 40 lb. a divided load or shoulder carrying was more economical; at 50 lb. shoulder carrying was cheapest. Details of the observations made and illustrative graphs are given.

CONGRESS OF THE ROYAL SANITARY INSTITUTE AT HULL.

IN THE LANCET of August 4th (p. 251) we dealt with the opening of this Congress and the President's address. The business of the Congress was transacted in four sections—viz., Sanitary Science, Engineering and Architecture, Maternity and Child Welfare (including School Hygiene), and Personal and Domestic Hygiene, and in seven conferences—viz., those of Sanitary Authorities, Port Sanitary Authorities, Medical Officers of Health, Engineers and Surveyors, Veterinary Inspectors, Sanitary Inspectors, and Health Visitors. The multiplicity of subjects was so great that it may be truly said that every delegate had some opportunity of voicing what was in his mind. It was perhaps inevitable that occasionally the programme should be overloaded, but we would respectfully suggest to the management that at future congresses the business should begin at 9.30 A.M. and end at 1 P.M. The nominal hours were from 10 to 2, but the hour from 1 to 2 P.M. is purely nominal. We would also suggest the limitation both of the number and duration of the presidential addresses. Space permits reference to only a very few of the subjects discussed.

Housing.

The housing question, as was natural in the present parlous condition of housing, received much attention. The city engineer of Edinburgh, Mr. A. H. Campbell, advocated the acquisition by local authorities of all slums in their areas with a view to putting them into a better state, pending the erection of a sufficiency of new houses. Alderman Cheverton-Brown, secretary of the National Federation of Property Owners, voiced the difficulties of property owners, including the problem of the dirty and destructive tenant. His remedy for house shortage was the removal of restrictions, the restoration of confidence amongst investors, and the encouragement of private enterprise. Miss A. Churton, secretary of the Rural Housing and Sanitation Association, also favoured the acquisition of unhealthy areas and their management on lines associated with the name of Miss Octavia Hill. The woman's part in smoke abatement was ably dealt with by Mrs. Cloudesley Brereton, and the much more extended use of electricity in the home was advocated in a practical manner by Lieut.-Colonel Vignoles, borough electrical engineer of Grimsby. The latter's ideal was a house with one fire for the hot-water cistern, and in which electricity is used for lighting, cooking, heating in the other rooms, and as an auxiliary to the hot-water supply.

Preparation of Food.

The hopeless state of housing probably stimulated interest in the food question. Miss Florence Petty indicated how better knowledge of cookery might be conveyed to existing mothers. Mr. A. R. Tankard, F.I.C., showed that 20 per cent. of our foods, exclusive of milk, are chemically preserved. The need for much greater cleanliness in the preparation and distribution of food was discussed by Dr. W. St. C. McClure, who advocated the licensing and supervision of all premises where food or drink is prepared or served. The importance of food, and especially of a vitamin-rich diet, as a means of increasing resistance against tuberculosis and of preventing a minor infection from developing into recognisable disease was strongly emphasised by several speakers.

Other Topics.

Dr. O. K. Wright (of the Ministry of Health) supplied an interesting paper on scientific methods in public health propaganda, and Dr. W. Allen Daley (M.O.H., Blackburn) dealt with this subject in special reference to cancer. Light treatment was dealt with at various sessions, and Sir Henry Gauvain gave an instructive address on Alton methods. A thoughtful and suggestive paper on infantile mortality by Prof. F. E. Wynne (M.O.H., Sheffield)[1] provoked a good discussion, but seemed to be misunderstood by several members of his audience. Papers by Dr. S. G. Moore (M.O.H., Huddersfield) and Dr. H. Scurfield (formerly M.O.H., Sheffield) dealt more particularly with that portion of infant mortality which occurs in the first month of life. While Dr. Scurfield left it an open question as to how the new midwifery—i.e., the execution of the skilled obstetrical work during pregnancy instead of as an emergency procedure during labour—was to be carried out, Dr. Moore advocated the Huddersfield system of notification of pregnancy, by means of which the expectant mothers are visited at home by duly qualified doctors appointed by the corporation.

Tuberculosis and Milk.

In the discussions on the prevention of tuberculosis some speakers favoured the cutting off of the supply of seed and others favoured making the soil unsuitable; the Greek representative, Dr. Alexander Cawadias, intervened usefully to point out that we

---

ust have a combination of both methods. It is ways a little unfortunate, and must be mystifying the lay public, that medical speakers do not make vo points clear in these discussions on the prevention tuberculosis—viz.: (1) that a safe milk-supply an only prevent the human mortality caused by ovine tuberculosis, estimated at 6½ per cent. of the otal tuberculosis mortality, or 3000 deaths annually England and Wales; (2) that the 90 per cent. of fections with tuberculosis which occur in childhood o not as a rule become recognisable disease, and ther heal up or become latent. The possibility of tency indicates the need for increasing resistance, ut the undue influence of the universality of infecon doctrine leads to fatalism, and a conviction that easures to prevent infection, even massive doses infection, which, along with other conditions, give e latent disease its chance of becoming active, are itile. The importance of milk as a food had due rominence. Dr. Stenhouse Williams put the case bly for what may be called the Reading system of rade A tuberculin-tested milk at a cost little above at of ordinary milk; Dr. S. G. Moore presented e case for pasteurised milk, while there were not anting advocates of dried milk. Again, it is unformate for the information of the public that medical eakers should speak loosely of the destruction of itamins by heating processes, without mentioning hich vitamin, seeing that it is now generally recogised that in most heating processes the vitamin estruction is limited to a portion of the vitamin C ntiscorbutic), and easily compensated for by range juice, &c. The "nature" argument in vour of raw milk was met with the response that ow's milk, its derivatives butter and cheese, and eggs re quite unnatural foods for man, and that the only asonable method is to apply the tests of modern ience to the foods which man uses, and decide hether they are good, bad, or indifferent. The perience of China was mentioned as a country ddled with tuberculosis, in which cow's milk was ot used, but no information was available as to hether the type of tuberculosis is more virulent ere, in a population presumably not immunised in y degree by bovine tuberculosis. In any case he ould be a bold man who would suggest the general e of raw milk for children, seeing that the present rtial use of it constitutes an immunisation experient which causes the deaths of 3000 children nually in England and Wales, and a corresponding amage rate. Dr. J. Cates (M.O.H., county of Surrey) ntributed a paper on the training of women for blic health work, which ended with the expression his conviction that the trained nurse will come to her own and will be allowed to follow a career r which she is particularly well adapted.

Dr. R. A. O'Brien (of the Wellcome Research aboratories) advocated the use of the Schick test sanitary authorities, and expressed the opinion at the time will come when the occurrence of a se of diphtheria amongst the staff of a fever children's hospital will indicate unforgivable glect.

In a paper on Practical Disinfection Prof. H. R. enwood criticised the tests at present in use for sinfectants, and the misleading statements made manufacturers on the strength of such tests. He ought manufacturers making false claims should liable to heavy penalties, as is the case in America.

A paper by Dr. E. Colston Williams aroused conlerable interest, and showed that the movement in vour of pit-head baths is making headway.

Dr. G. A. Auden (school medical officer, Birmingam) recorded the particulars of an interesting periment, under which children suffering from alnutrition were given an extra milk ration. The periment lasted several months, and the results, th physical and mental, were remarkable. The periment was very carefully conducted, and Dr. uden hoped it would be the precursor of other periments on a larger scale.

PUBLIC HEALTH LEGISLATION IN THE IRISH FREE STATE.

A DEPUTATION from the Irish Medical Committee, consisting of Dr. J. M. Day, Senator W. O'Sullivan, M.D., Dr. R. J. Rowlette, Dr. J. P. Shanley, Dr. T. Hennessy (medical secretary), and Mr. C. H. Gick (secretary), waited on the Minister of Local Government (Mr. E. Blythe), Irish Free State, on August 1st. The deputation was accompanied by representatives of the Connemara medical officers. The deputation was introduced to the Minister by Prof. M. Hayes, T.D., National University (Speaker in the Dail). Its main object was to make certain representations with regard to the Public Health Bill, which was to have been brought forward in the Dail at an early date.

The View of the Irish Medical Committee.

Dr. Rowlette, speaking on behalf of the deputation, said that although the forthcoming election might seem to make their visit untimely, they thought it right, when the Minister was willing to receive them, to make their views known. It was understood that the Department had been at work on a draft for a Public Health Bill; no measure would be adequate unless it was thorough-going, as the condition of Ireland gave cause for anxiety. The death-rate in other countries had fallen greatly in the past 60 years; in Ireland it was practically stationary; the mortality from tuberculosis had fallen in Great Britain by more than a half, in Ireland by only a third. Infant mortality in Ireland as a whole was not high, a fact observed in all pastoral countries, but in the Irish cities it was alarmingly high, Dublin having the highest infant mortality in the British Isles—134 per 1000, as compared with 80 per 1000 in London. Less care was paid to public health in Ireland than in any civilised country in the world; in the whole of the Free State there was only one whole-time medical officer of health—the officer for Dublin. In country districts sanitary work, in the modern sense, hardly existed. The dispensary doctor was medical officer of health for his district as well as dispensary doctor, and for the duties of this added office he was paid a separate salary, which varied in different districts from £5 a year to £30; rigorous attention to preventive work was thus made impossible.

The deputation urged the Minister to accept in its entirety the programme of the Irish Public Health Council, which had been accepted by the medical profession and by the press and had recently in its essentials been put forward by the General Council of County Councils, a body thoroughly representative of the ratepayers of the country. The central features of the programme were the establishment of a Ministry of Health and of a National Medical Service. The Irish Medical Committee saw no hope of making the public medical services attractive to the best class of young Irish medical men and women by any other means than by the establishment of a national medical service. The profession had welcomed the reforms carried through by the first Dail and on the proposals of the Minister, but they did not go far enough, save in one particular, the abolition of district hospitals, where, indeed, the changes went too far. The establishment of the county as the health unit was a great advance. The Irish Medical Committee thought that the setting up of a body such as the Irish Public Health Council, or a health council such as was recommended in the report of the Irish Public Health Council, would be helpful to the Minister.

Reply of the Minister of Local Government.

The Minister stated in his reply that in view of the early dissolution of the Dail it would be impossible for him to adhere to his intention of introducing a Public Health Bill, but he hoped that it would be one of the first measures to be introduced after the election. He fully realised the unsatisfactory condition of health questions in the Free State; it was his intention to deal with public health before undertaking the reform of the medical services. He proposed to appoint a medical officer of health for each county, with school medical inspectors and tuberculosis medical officers under him. He hoped that such salaries would be paid as would attract the best young doctors in the profession in Ireland. He did not favour the establishment of a Ministry of Health apart from that of Local Government; he considered it was only a difference in nomenclature which in practice meant very little. He favoured the formation of an advisory body similar in functions to the existing Irish Public Health Council, but thought that the question of a national medical service required further consideration. The deputation then continued the discussion with Mr. McCarron, Secretary of Local Government, and Dr. E. F. Stephenson, Medical Administrator.

Mr. O'Maille, T.D., brought forward the case of the Co. Galway doctors, especially those in the Connemara district, and protested against the action of the Local Government Department in refusing to sanction the full amount of £300 per annum for dispensary doctors in Co. Galway. Two representative practitioners from Connemara stated that their districts were 20 miles in length and 15 miles in breadth; one of them mentioned that the population of his district was over 8000, that as many as 80 per cent. of these were treated gratuitously under the Medical Charities Acts, and that to give sufficient attendance to the sick in his district he would have to be paid more than double his present remuneration to cover travelling expenses.

The deputation discussed at considerable length other questions concerning the Poor-law Medical Service—viz., inadequate salaries, arrangements for holidays, and fees for occasional services.

UNITED STATES OF AMERICA.

(From an Occasional Correspondent.)

Passing of Another Pioneer.

Within a few weeks of the death of Dr. Hermann Biggs, reported in my last letter, New York has lost another of her medical pioneers by the sudden death from heart failure of Dr. John H. Pryor, head of the board of directors and physician in chief at the Perrysburg Hospital. He was the founder of Ray Brook Sanatorium, the first public institution for the exclusive treatment of tuberculosis in this country, and situated only a few miles from the Trudeau Sanatorium at Saranac Lake. Afterwards, at Perrysburg, he turned his attention to the treatment of surgical tuberculosis by heliotherapy and artificial light, and developed an institution worthy to be compared with those of Sir Henry Gauvain at Alton or of Dr. Rollier at Leysin. Dr. Pryor was also one of the founders of the National Tuberculosis Association. He was 62 years of age.

Control of Urine Sugar under Insulin Treatment.

The importance of avoiding dangerously low sugar excretion has been amply demonstrated during the early experience with the treatment of diabetes by insulin. Mr. Irvine H. Page, of the Eli Lilly Research Laboratories, reports a method[1] for which he claims both simplicity and accuracy, with the additional advantage that it can be used for determining slight excess of sugar excretion in "borderline diabetes." This method consists in hourly sugar determinations throughout the day (7 A.M. to 7 P.M.), and a further test of the 12-hour combined night urine, by the Benedict-Osterberg method.[2] Mr. Page's experiments showed that the curve of normal sugar excretion is remarkably constant with a slight upward trend from morning to evening, and a low level during sleep. During the hour following meals there occurs a sharp rise which is in no way dependent upon the quantity or quality of food ingested. Great variations and remarkable constancy of sugar excretion may be found at different times in the same individual. Mr Page fixed as the upper limit of a normal curve 110 mg. of sugar in the hour. Among his supposedly normal subjects, towards whom no suspicion of glycosuria had ever been entertained, there were some who considerably exceeded this allowance, which leads Mr. Page to the conclusion that the method is likely to prove valuable for the determination of unsuspected glycosuria. It is, however, a little elaborate as a routine test. There can be no doubt, on the other hand, that it will give valuable information during insulin treatment. Mr. Page considers that the lower limit of safety in a patient undergoing insulin treatment is 30 mg. per hour. Fortunately the amount of insulin required to reduce "normal urine sugar" to a dangerously low level greatly exceeds that needed to reduce pathological wastage, but this fact does not excuse the administrator of insulin from taking every precaution to avoid a dangerous hypoglycæmia.

VIENNA.

(From our own Correspondent.)

Insulin Treatment in Vienna.

At a recent meeting of the Vienna Medical Society the insulin treatment of diabetes was discussed, and Prof. Falta described his experiments made in order to obtain the active substance. The animals used were dogs, fœtal calves, fish, and latterly sheep, pigs, and oxen. The results of the treatment are very encouraging. Large doses are necessary, each dose being equivalent to the quantity of insulin required to diminish by 50 per cent. the blood-sugar in a medium-sized rabbit. The employment of insulin is not free from risk; excessive doses produce hunger, fatigue, spasms, loss of consciousness—symptoms best treated by intravenous injections of grape-sugar. Other Viennese observers have also had excellent results with this remedy. Rapid improvement of patients in a comatose condition was seen several times. The excretion of sugar and acetone can be promptly reduced to a fraction of the regular output. Insulin cannot supersede the dietetic treatment of diabetes, but the new method is a most welcome addition to the physician's equipment. Insulin is being prepared in three laboratories in Vienna, as it is too expensive to be imported from abroad. Physicians are agreed, however, that the English product is much better than that hitherto obtainable here. Dr. Pollak pointed out that the increase of weight noted in patients submitted to that treatment is due to water-retention in the tissues, and that all patients benefit by being allowed fat and carbohydrates.

Influence of Diuretics on Water Content of Tissues.

Dr. Saxl has investigated the influence of diuretics upon the tissues in healthy and diseased persons in order to clear up the conflicting evidence found in the literature of the subject. As a rule, healthy tissues are only slightly affected; theobromin, for instance, does not increase the flow of urine in children (Hecht), whilst novasurol is very effective. In œdematous patients diuresis was supposed to be produced by direct attack upon the œdematous tissue. Experiments by Schur show, however, that purin bodies do exert a very definite action on healthy kidneys; Schur thinks that they act chiefly on the kidney and not by mobilising the water contained in the tissues. In a recent discussion on this problem at the Vienna Medical Society all these hypotheses were brought forward; the majority of the investigators agreed that the chief burden is assumed by the kidney. All diuretics should be capable of stimulation of the function of the kidney. The idea that water might be "drawn out" of the tissues cannot now be upheld. It is the vis a tergo which causes large anasarca to disappear under the influence of a diuretic remedy, increased pressure by improved heart action being one of the chief factors. The influence of the nervous system upon the kidney must not be lost sight of, ecause the same remedy acts in one case and fails to ct in another.

General Systemic Effects of X Rays.

The effects of X rays upon the general condition f patients who had for various reasons received rge doses of them were recently studied in Prof. chlesinger's clinic. In nearly every instance marked ebility and malaise appeared similar to that following itoxication, and sometimes so severe as to give the ppearance of shock. This condition, expressed y an abnormal distribution of blood and changes the permeability of the blood-vessels, was quickly nproved by hypertonic solutions of sugar, NaCl r Na_2SO_4, this being very similar to improvement bserved in actual shock. Further investigations ave shown that not only is NaCl largely eliminated om the blood after a strong dose of X rays, but lso that the concentration of potassium, calcium, nd cholesterin in the blood is profoundly altered, hile the blood-sugar reacts sharply. Lymphatic ssue is also severely affected, and the products of his disintegration are no doubt partly responsible r the symptoms of intoxication after X ray application. Every exposure to X rays which penetrate rough the superficial layers must, therefore, be garded as a systemic injury first manifested by the ansportation of NaCl from the blood to the kidneys nd thence out of the body. One of the organs rimarily affected is the liver, which soon shows arenchymatous changes. This organ may be "absotely insufficient" to deal with the work thrown pon it even by a small quantity of X rays, or relatively insufficient," if an intensive dose has used a large amount of disintegration products be circulating in the system. The liver may thus e seriously affected, not by the rays themselves, ut by the metabolic changes caused in the blood. he normal function of other glandular organs may so be seriously hampered after an X ray application the body, but all evidence points to the liver as the ief sufferer, hence the malaise and prostration so ften complained of after X ray sittings. The change in lt concentration is only part, however, of the damage one to the system; it is readily counteracted by iving the patient an adequate dose of NaCl, whilst her damage is not yet easily recognised or treated.

July 31st.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Terminal Hæmaturia.

IN a recent number of the *Gyógyászat*, Dr. Kertész, Budapest, dealt with terminal hæmaturia as e of the most obstinate symptoms of gonorrhœa. his hæmaturia always occurs after micturition, and sults from the strain which serves to express the last rops of urine. The blood exudes from wrinkles rmed between the bladder and the urethra, which rinkles are exposed, about the end of micturition, to certain tension; their epithelial surface is mostly coriated, and during the frequent contractions nnected with pressure they void a few drops of ood. Methods of treatment hitherto applied—rest bed and instillation of silver nitrate—are frequently no avail. Another more efficacious method consists letting the patient micturate in a half-recumbent sition, instructing him when the act is nearly ncluded to relax muscular pressure and to press the ladder hard with the hands. In this way the last rops of urine are expressed. This method is very rviceable, often relieving the patient from terminal ematuria in a few days.

Neosalvarsan in the Treatment of Chorea.

Dr. János Bókay, professor of diseases of children the University of Budapest, has lately administered eosalvarsan in severe cases of chorea with excellent sults. A striking relief of incoördination a few days ter the first intravenous application of neosalvarsan, and disappearance of the intense nervous restlessness in every instance after the second injection—i.e., after ten days—have been observed. The quantity of neosalvarsan given varied; Dr. Bókay used a dose of 1 g. on an average. Up to now, chorea in a child of "middle" age could generally be cured by oral application of some 300 drops of Fowler's solution, with an arsenic content of about 0·12 g. The arsenic content of 1 g. neosalvarsan is 0·217 g. Prof. Bókay attributes the rapid effect of the latter not to the greater arsenic content, but to the fact that the arsenic in the neosalvarsan is organic and also lipotropic, making possible the penetration of the arsenic into nerve tissue.

Death of an Eminent Ship's Surgeon.

Dr. Francis Gáspar, who died recently, was well known for his books of travel, and served about 40 years with the late Austro-Hungarian marine as a ship's surgeon. He published his experiences in two large works. "Seven Years on the Sea," and "Forty Thousand Miles with Steam and Wind"—i.e., 200,000 English miles—both of which were translated into several foreign languages. After the war, when the Austro-Hungarian marine service disappeared, Dr. Gáspar accepted the offer of an important post in the Hungarian Public Health Department, but found the work distasteful, and became embittered to such an extent that he committed suicide.

A Wheat Currency.

The Hungarian doctor's livelihood at the present time is precarious, especially in the provinces, where a village practitioner's annual income rarely exceeds 100,000 kronen (at present equivalent to something over 45*s.*). The instability of the economic situation has led the local branch of the Medical Association at Szabolcs to introduce a new system of payment of medical fees. The fee for a consultation is to be the current price of 5 kg. of wheat. Even this very moderate fee will be reduced for officials, clerks, &c., whose salaries do not vary with the fluctuations of the price of wheat.

Census Figures.

The Central Statistical Bureau has just published the data yielded by the last census. Hungary is stated to have had 7,980,143 inhabitants in 1920, which figure represents a 5 per cent. increase against 1910 in the present Hungarian territory. This increase of population, despite the tremendous loss of life in the war, is due to the influx of people from the lost portions of the old Hungarian kingdom. Another result of the war was that the male population numbered 3·8 millions and the female population 4·1 millions. The number of widows in the country was 25 per cent. larger than in 1910, and the number of divorces had increased by 55 per cent.

Child Welfare Exhibition.

On July 16th the first Hungarian Child Welfare Exhibition was opened in Budapest. The exhibits were divided into various groups—hygienic, educational, &c. A large collection of apparatus for the correction of deformities, a number of skulls of children from the pathological museum of the pædiatric clinic, a series of models illustrating the different infections of childhood, and statistics relating to children's accidents were among the most interesting features of the exhibition.

July 27th.

THE LATE DR. J. R. STENHOUSE.—The death occurred at St. Andrew's-place, Lewes, on August 10th of Dr. John Robert Stenhouse at the comparatively early age of 52. Dr. Stenhouse received his medical education at Guy's Hospital, becoming M.R.C.S., L.R.C.P. Lond. in 1894, and B.S. Lond. in 1895. He secured the diploma of Public Health in 1904 and obtained the degree of M.D. (qualifying for medal) in 1907. Dr. Stenhouse held a number of appointments at Lewes, including those of school medical officer and medical officer of health, but ill-health compelled him to relinquish the latter post some years ago. He was an occasional contributor to the medical press.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT PORTSMOUTH.

(*Continued from p. 304.*)

SECTION OF MEDICINE.

Wednesday, July 25th.

In opening the discussion, before a crowded audience, on

Diabetes,

the President, Sir Thomas Horder, said that the committee of the section had had no difficulty in choosing the subject of the first debate. If insulin were not discussed our patients would be much surprised, and with good reason, and they would probably assume, and again with reason, that we were quite satisfied that in insulin we possessed a "cure" for diabetes and that nothing more need be said on the subject. Many persons had already assumed this in view of certain generalisations which, if they did not carry the hall-mark of authority, had not been authoritatively contradicted. It was notoriously difficult to control popular ideas about new remedies, and the very fact that such epoch-making events as the discovery of insulin were rare, when they did come, took popular credence further than facts justified or the discoverer claimed. The problem was regarded as already solved, whereas it might well be that insulin would prove to be as great an asset to medical science by assisting the interpretation of obscure phenomena as in the provision of a therapeutic agent. Had not the essence of the problem of diabetes been the almost certain fact that we were dealing not with one biochemical change but with several? Certain cases of diabetes were benefited much less by insulin than were others, and certain would be found not to be benefited at all; this position must be made quite clear in our patients' interest.

Some very fundamental questions, Sir Thomas Horder continued, will be discussed, and we shall hear the opinion of men well qualified to speak upon them. Will some of the cases of diabetes that show such striking improvement under treatment by this remedy recover their lost power of maintaining a normal blood-sugar so as to "carry on" without its help? Is diabetes necessarily a progressive disease? At what level should the blood-sugar be maintained in order that insulin should be most effective? Will blood-sugar estimations continue to be necessary in every case, and, if so, are either of the rapid methods at present in use practicable and accurate for the general practitioner? Will it be a safe criterion by which to control an increase in the patient's diet to adopt the estimation of urinary sugar? Can any general guide be given as to the best proportions of the main food principles which it is wise to employ in venturing upon an increase of diet when, by the use of insulin and by starvation, the blood-sugar has kept within a normal range for several days, or must each case be regarded as a law unto itself? Is there not a hope that the active principle of insulin may be isolated so that it may be effectively given by the mouth? We shall doubtless hear of the abuse of insulin by the greedy glycosuric and of the undesirable symptoms produced by the use of insulin in cases of renal glycosuria. It would be a vain request to ask that in this discussion some consideration should be given to other aspects of diabetes than those concerned with insulin: the relation of sepsis to diabetes, the ultimate causation of pancreatic cases, the influence of infection and heredity. Insulin is probably the greatest contribution yet made to the study of diabetes. The section extends a very hearty welcome to Dr. Banting, and he will be asked to speak first. If he has anything new to tell us we shall be very interested to hear it. If he has nothing new then we shall like to hear the old story again from his own lips.

Dr. F. G. Banting (Toronto) said that he and those associated with him in his work thanked the medical profession for the way in which it had received the result of their experiments. He outlined the story o the research which led to the preparation of insuli in quantity. Following ligature of the pancreati ducts the acinous cells of the gland degenerate, bu the islet cells remain intact. They had ligated th ducts in a dog and ten weeks later removed th degenerate pancreas and extracted it with saline The injection of this extract into a diabetic dog cause a fall in the animal's blood-sugar and it lost it ravenous appetite. The amount of pancreas s obtained was very small. The injection of secretin t exhaust the acinous cells was found to be ver uncertain in its results. Up to the fourth month o intra-uterine life the acinous cells in the fœtal cal contain no trypsinogen granules. An extract of thi material was found to be very active in lowerin blood-sugar. An attempt was then made to extrac whole pancreas with some chemical substance whic would destroy trypsin but leave insulin unharmed 82 per cent. alcohol was found to answer the purpose Since then rapid progress has been made and th product is now protein-free, is non-irritating, and easil standardised. In the laboratory insulin in prope dosage reduces the blood-sugar to normal or less renders the urine sugar-free, and by its use the lif of a depancreatised dog can be greatly prolonged. Insulin also enables the liver to store glycogen. In adequate doses insulin will control all forms of hyperglycæmia.

Clinically there is no fixed method of managin diabetic patients. In Toronto a case, if at all severe, is admitted to hospital for at least three weeks' training and the working out of sugar tolerance. The patient is kept on his usual diet for 24 hours and then upon the "basal requirement diet"; 0·75 g. of protein per kilo body-weight is given to an adult pe diem, the remaining calories are made up of carbohydrate and fat. A mild case on this diet becomes sugar-free; if severe the output becomes more constant. If the patient can take 500 calories over and above the basal requirement insulin is not given. The suga output is of value in estimating the initial dose of insulin. One unit will metabolise from 2 to 2·5 g. of carbohydrate in a severe case and from 5–6 g. in a mild case. As a rule, 5 units may be given to begin with unless the patient is comatose. The dose should be given one hour before a meal once a day. It is advisable to keep the patient sugar-free, as in that state the pancreas tends to produce insulin. In many cases there is evidence of increasing tolerance as a result of treatment with insulin. The frequency of blood-sugar estimation necessary to control treatment is still uncertain.

Dr. P. J. Cammidge (London), after expressing his personal admiration for Dr. Banting's work, said that for many years the name diabetes mellitus had been applied to any condition of glycosuria. It was now possible to determine with considerable certainty whether the symptom depended on failure of the pancreas or was due to other known causes of hyperglycæmia. Clinically the prognosis and reaction to treatment of the various types was different. He had applied the test of "hydrolysis and difference values" of the blood to its sugar content before and after a standard breakfast. In this test the blood-sugar is estimated in one sample and in another the reducing power is determined after being freed from protein and hydrolysed. The latter gives the "hydrolysis value" and the difference between the two is the "difference value." By this means three types have been differentiated, characterised respectively by deficiency of the internal secretion of the pancreas, hyperactivity of the thyroid, pituitary or nervous disturbances, and defects of carbohydrate storage in the liver. Combinations of these types were met with, but deficiency of islets develops in all untreated cases of hyperglycæmia. Insulin may be used in treatment in three ways: as a temporary aid to metabolism in emergencies, to enable a patient to take a diet in excess of his natural tolerance and as a remedial measure. It is not a universal cure for diabetes, but is the most valuable means we have for ontrolling metabolic defects due to deficiency of he internal secretions of the pancreas and should not e given indiscriminately to all cases of glycosuria.

Dr. **George Graham** (London), speaking on the esults of experiments on patients in the medical rofessorial clinic at St. Bartholomew's, said tolerance ould be recovered to a certain extent by resting the let cells. It was of the utmost importance to make ertain that as a result of treatment the blood-sugar as normal in the morning before the daily dose of sulin was given and no carbohydrate beyond that the vegetables must be added until the morning lood-sugar had been normal for three or four weeks. the blood-sugar was 0·2 per cent. or 0·15 per cent. e islet cells were overworked and had no chance to pair. In order to produce this a varying dose will e required in different individuals; in some 10 to 15 nits a day would suffice, in others 30 to 50 units even vice a day might be required. Blood-sugar estima- ons were of assistance, but not absolutely necessary; long as glycosuria occurred they could be dispensed ith, but when the urine was sugar-free it was im- ortant to make estimations occasionally as there was o other means of telling whether it were 0·10 per cent. r 0·18 per cent. Blood should be collected either efore the insulin injection or 12 hours after. It was etter to estimate the blood-sugar at once, but the lood might be collected and preserved by the addition potassium oxalate and one drop of 40 per cent. rmalin. Results of treatment in cases of coma were, far, fairly good; two recovered and one died. It as important to hunt for sepsis in every case; the tal case had a parotid abscess. In coma 20 to 30 nits should be given subcutaneously at once; it was nnecessary to give sugar if the patient was passing uch sugar, but if very bad 50 g. of sugar and 60 units insulin should be given at once, and as much as 140 nits may be required in 24 hours.

Dr. **J. A. Nixon** (Bristol) said he had treated five ses of diabetes with insulin, and spoke enthusiastic- lly, though perhaps prematurely, as to its value. as a patient any better, he asked, for being sugar- ee when he had a high blood-sugar? The patient ay gain in weight and well-being, but was he safe? glycosuria occurred with a low blood-sugar threshold e could make use of a trace of glycosuria as a guide insulin dosage. Symptoms due to hypoglycæmia ere difficult to determine. A man of 40 received units of insulin daily for three days and then ddenly developed partial aphasia; he was given ucose and speech improved the next day, but as he ad had angina pectoris the aphasia may have been vascular origin. Another man, aged 35, receiving units complained of tingling in the legs and swelling the feet though his blood did not show hypo- ycæmia. The "basal requirement diet" was the ost practical standard diet (Woodyat formula), hich enabled insulin dosage to be adjusted to a diet hich was adequate.

Dr. **John Rennie** (Glasgow) contrasted the results treatment of a series of cases under the old, the llen-Graham, and insulin methods of treatment. n improvement may be expected in the majority eated by the Allen method, but end-results were far om satisfactory. Ten cases treated with insulin owed distinct improvement. To determine the quisite dose of insulin each patient was given a eal of known carbohydrate protein fat content with creasing doses of insulin until satisfactory blood- gar and urinary-sugar results were obtained, and om this a sufficient dose for an adequate diet was lculated. This method was best suited to chronic ses with low carbohydrate tolerance. There was experimental evidence to show that insulin was sorbed through the skin.

Dr. **E. P. Poulton** (London) said that in certain ses a distinct increase of tolerance had been observed ter prolonged treatment with insulin.

Dr. **O. Leyton** (London) referred to the curative operties of insulin in diabetes of comparatively cent origin and due to pancreatic defect. When there was a probability that damaged islet cells were present an attempt should be made to restore them to health by rest—i.e., giving enough insulin to make blood-sugar below rather than above normal; if symptoms of hypoglycæmia result they may be controlled by the administration of sugar.

Dr. **A. P. Thomson** (Birmingham) had observed a definite increase in tolerance in two cases that had previously been vigorously dieted for some time. Blood-sugar estimations were essential when giving large doses of insulin, but treatment can well be carried on without in the average case if the urine were examined frequently and the diet properly controlled. A few estimations were necessary during a preliminary period of standardisation.

Dr. **Frank Roper** (Exeter) related some recent experiences with insulin, and Dr. **E. E. Waters**, I.M.S., and Dr. **A. Clarke Begg** (Swansea) took part in the discussion before Dr. **Banting's** reply.

THURSDAY, JULY 26TH.

On the second day the section, under the chairmanship of Dr. **J. Odery Symes** (Bristol), discussed

Heart Disease in Early Life,

its ætiology, prevention, and treatment. Dr. **Reginald Miller** (London) said the matter was of prime importance for the people of England. The subject resolves itself largely into the consideration of one disease, and that is acute rheumatism. In reviewing the progress made in the fight against this disease the chief change in the last 50 years seems to be a reduction in the frequency of its severer manifestations; hyperpyrexia, the most dread of all rheumatic symptoms, seems to be disappearing, and the number of cases of rheumatism sufficiently severe to require admission to hospital is also declining; in the last 50 years the admissions have dropped 50 per cent., according to the statistics of some London hospitals. The incidence of acute pericarditis as judged from the same tables is also declining. Some progress, therefore, appears to have been made, and it is due rather to clinical work than to public health administration; earlier diagnosis and more efficient treatment being in the main responsible. But rheumatism still remains one of the serious infections of this country, and the factors hindering progress are numerous, and may be considered under three headings.

1. *Problem of Rheumatic Infection*—the most important. The modern view is that it is a specific infection producing no sort of immunity against itself. A disease reproducing the same clinical picture again and again must be due to one type or strain of microbes; the histopathology proves the bacteriæmic character of the infection and supports its specific nature. To gain more knowledge as to the influence of the rheumatic environment it might be of service to make rheumatism a notifiable disease, and education of parents and school teachers would further our efforts to get the rheumatic child under treatment as early as possible. As to the specific organism, the view was expressed that it is an alimentary streptococcus, one fact brought forward in support being the isolation of such an organism from the cerebro-spinal fluid in a case of chorea. The action of salicylate was discussed and the view expressed that it exerted a bactericidal action; the effective dose in children is from one to two drachms a day divided into many small doses. As to the origin of the recrudescences of the infective process and reinfection of the rheumatic, early attacks may often be traced to the tonsils and tonsillectomy may do good, but the source of later attacks is often wrapped in mystery. The tests of cure are the loss of the toxic appearance, a gain in weight, and a flat temperature chart.

2. *Problem of Heart Disease in Rheumatic Subjects.*—Heart disease in rheumatism is largely a matter of the severity of the infection and the age of the child; below 12 rheumatism is essentially an infection of the heart. The severe symptoms often develop with a

rush, yet they are nearly always preceded by mild symptoms. The activity of the infection must be subdued by salicylate, while sparing the heart by rest, early diagnosis, and efficient treatment.

3. *Problem of Cardiac Crippling in Rheumatic Heart Disease*—the chronic heart invalid. The heart muscle loses its power of recovery. It is infection rather than mechanical strain that has done the harm; the child's heart never breaks down by mechanical strain alone, and these cases of chronic cardiac disease are the result of repeated infections. In preventing and treating chronic cardiac insufficiency reliance must be placed on the persistent use of salicylate in the hope of preventing recrudescences of infection, the use of digitalis when indicated, and removal of tonsils obviously diseased. Vaccine therapy, even as a prophylactic, in spite of recent reports with *S. viridans* from America, is most disappointing. With children too toxic to react the infection produces no immunity to itself. Sir A. E. Wright's new method of transfusion with immunised blood may be well worth a trial. The provision of prolonged quiet rather than strict rest, correct hygiene, close medical supervision, and some facilities for education should be aimed at. The most urgent problems awaiting solution are: (1) What is the underlying connexion between rheumatism and poverty? (2) What is the origin of repeated relapses and how can they be prevented? (3) How can we give long courses of treatment to our many heart cripples?

Dr. G. A. **Allan** (Glasgow) said that in 1921 53,710 deaths, or 11·7 per cent. of deaths at all ages from all causes in England and Wales, were due to heart disease. Rheumatism accounts for about half to one-third of deaths due to heart disease in a general hospital. In Glasgow, with a population of 1,111,428, the education authority is responsible for 198,304 children, and in routine examination 0·6 per cent. had acquired organic heart disease, and 1·1 per cent. functional heart disorder. In London 4 per cent. of girls and 3 per cent. of boys of 12 years of age have a cardiac disorder. There must be between 45,000 and 50,000 children attending school in Great Britain who have organic heart disease, many of whom are destined to become cardiac cripples before middle life. The percentage of cases doubles during the compulsory school age. Rheumatism was an infection, but an organism did not necessarily have to be seen before it could be fought. Was tonsillitis a rheumatic manifestation, or was the tonsil the site of entry or the home of the organism? Did scarlet fever ever produce heart disease or predispose to rheumatic infection? With our present knowledge some education of parents was possible. Many do not realise a child could have rheumatism. Education of students should be more thorough, and they and practitioners should realise that treating rheumatism by pharmacopœial doses of salicylate is only playing with a serious disease. End-results of rheumatism as seen in general hospitals were very seldom the result of only one attack; cases of pericarditis in a first attack do not as a rule live long. We wanted to know the habitat of the organism and the predisposing factors to the disease. A committee linking up various workers would be in a position to influence medical and lay opinion in the direction of most useful activity. It was proposed that the council of the association be recommended to appoint a special committee to consider the best steps to be taken to combat the grave menace to the community arising from chronic cardiac disease.

Dr. J. G. **Emanuel** (Birmingham) said that to a child suffering from organic heart disease the danger is not from over-exertion but from re-infection. Rheumatic carditis demands rest in bed. If no active infection was present a damaged heart required exercising. Rheumatic carditis often ran an afebrile course. Anæmia might be too slight to be a guide, and the same holds for the loss of weight. Physical signs, with the exception of pericardial friction, did not help us to recognise active cardial infection. A pulse-rate over 100 when the child was at rest in bed, especially if not slowed by digitalis, indicated active infection. Re-infection did not take place through the tonsil. Rheumatism in children closely resembles tuberculosis; in both repeated infection took place from existing foci within the body. Salicylate had not diminished the incidence of rheumatic carditis; it relieved pain and pyrexia in this and other conditions. There was a danger in its administration, in that by relieving pain and fever the child might be allowed up too soon. Hospitals, auxiliary to existing general hospitals, were badly required where children might lie until all infection was over.

Dr. **Carey Coombs** (Bristol) protested against Dr. Emanuel's anti-salicylate views in the treatment of cardiac rheumatism. Mortality records of Bristol proved the incidence of fatal cardiac rheumatism to be less than it was; in that city about 80 deaths occurred each year—in each case death might be preceded by, perhaps, ten years' crippledom. He welcomed Dr. Allan's resolution. Many cases of cardiac rheumatism became relatively cured, but the valve was always damaged and liable to become the seat of chronic ulcerative endocarditis. He warmly endorsed Dr. Emanuel's plea for treatment in auxiliary hospitals in coördination with existing teaching hospitals, and thought much might be done at once if Poor-law infirmaries were more readily available for the purpose.

Dr. W. H. W. **Attlee** (Eton) said that in public schools hearts crippled by rheumatism were very rare, but large numbers of functional hearts were met with wherein abnormal signs were found in the course of routine examination but which gave no symptoms. Variation from the normal physical signs in the heart of a rapidly growing boy meant very little in the absence of symptoms. Restriction of games in such cases does harm to the patient, and school life is spoilt to a great extent. He had followed up many cases which had hearts of this kind at school, and none had shown cardiac symptoms since leaving school.

Dr. M. O. **Raven** (Broadstairs) said that fresh air was necessary, and ordinary convalescent homes were too noisy for the treatment of children with heart disease. In rest homes at the seaside one had to decide how long a child was to be kept in order to prevent recrudescence. In New York it was considered that the child was not free until three years had passed without relapse. Of cases treated at Broadstairs 19 had been traced through periods of 18 months; these had remained for periods varying from six weeks to 12 months and were re-examined after living active lives in London for at least seven months. The result suggested that children were subject to relapse in proportion to the shortness of their stay in the country. Every child who ever had symptoms of the rheumatic state should be sent into the country for six to eight months before being re-exposed to the environment in which the disease was originally contracted. Routine rest was always to be deprecated. Rest is needed solely if infection was in the heart. A systolic murmur often disappeared with rest. A diastolic bruit at the apex was very common in children with active heart disease; its first manifestation was a reduplicated second sound which gradually became a mid-diastolic bruit and finally a pre-systolic murmur. On rest the murmur might recede completely. Until change in physical signs has ceased rest must be enforced.

Dr. F. G. **Layton** (Walsall) said that when patients were ordered by a hospital physician to bed for a month on account of rheumatism the general practitioner should be written to and asked to enforce that treatment and the administration of salicylate. What was the evidence that growing pains were due to rheumatic infection? Morbus cordis undoubtedly followed scarlet fever and diphtheria. Heart disease in children was much commoner in the back streets and far more hospital accommodation was wanted.

Dr. C. O. **Hawthorne** (London) emphasised the importance of prophylactic efforts, but did not approve of leaving propaganda work to a special committee and thought it should be done through the general practitioner. There were two pictures of rheumatic infection, the adult and the child—rheumatism in adults compels rest on account of arthritis, but the non-arthritic rheumatism of childhood did not enforce rest and for purposes of prevention rest must be secured. Leaflets for propaganda purposes were useless.

Dr. A. P. Thomson (Birmingham) reviewed his personal experience during the last two years in dealing with the problem of the rheumatic child at the Barberville institution in Birmingham—a residential school for cripples wherein some 50 per cent. of the beds were allocated to rheumatic cases. The outstanding clinical difficulties were two: to determine when the cardiac infection had become quiescent and when the child became free from the danger of re-infection. Cases of chorea did better when special educational methods were employed than when they did not go to school. By varying the daily amount of rest he found that one group, if rested for 18 hours in the 24, developed a more rapid pulse than those who were up; if a child was put to bed and his pulse-rate rose he should be exercised. Carditis does not develop when weight is going up. Rheumatic cases should be certified and treated in special institutions in touch with the medical schools.

Dr. E. J. Moffett (Birmingham) said that the type of case met with now was milder than in the nineties. As a school medical inspector she found difficulties in diagnosis between the effects of tubercle and rheumatism. The Birmingham mothers are well up in all symptoms of rheumatism. Treatment in the poorer classes was unsatisfactory. Severe cases are admitted to hospital; in less severe cases home treatment was attempted under the supervision of a school nurse. Long periods of continuous treatment are required. Education was important; rheumatic children were backward from prolonged absence from school and should be taught separately in smaller classes on a modified Delton plan. The gap between the curricula between the infant and other schools was too wide.

Sir Thomas Horder commented on the significance of the diastolic bruit in rheumatic heart disease, tressing its importance as a premonitory sign of mitral stenosis. Mitral stenosis differed in its evolu-ion from mitral regurgitation; the latter resulted rom acute endocarditis, a complication of rheumatic ever, whereas most cases of mitral stenosis followed not an acute endocarditis but a chronic, often afebrile, ometimes subacute, rheumatic process. Mitral regur-gitation was a vegetative affair of the cusps; stenosis n infiltration of the valve.

Dr. G. J. Langley (Manchester) said that the ecognition of subacute rheumatism in children might be exceedingly difficult. He drew attention to the parallelism between tuberculous and rheumatic nfection; both might improve on graduated exercise, hough the response to effort of the rheumatic treptococcus and the tubercle bacillus was not the ame. The response of the rheumatic patient to uto-inoculation was recognised in the form of a ecrudescence of the disease; in tubercle the response was often recorded on the temperature chart.

Dr. C. F. Routh (Southsea) commented on the ifficulty of tracing the origin of valvular defects in dults who were not aware that they had organic eart disease; a child's heart had an extraordinary ecuperative power. Acute rheumatism was very are in private practice.

Dr. R. Whittington (Hove) agreed with Dr. ttlee that properly regulated exercises were greatly o be preferred to forbidding games to boys at school.

Dr. Miller, in reply, said that he thought Dr. ttlee's cases were not infected or poisoned hearts nd should be treated on a nervous rather than a ardiac basis. Swimming was not good exercise for unctional cardiac disorders. Agreement was general s to the value of salicylate and the necessity of rest or the infected heart, and he was glad that the meeting felt the time had come for some investigation nto the rheumatic problem to be made.

Friday, July 27th.

On the third day Dr. G. A. Allan was in the chair and Dr. J. J. Perkins (London) opened a discussion on

Chronic Bronchitis.

The subject, he said, had been chosen at the request of the branches on account of the frequency of these cases in practice and their high death roll—1010 persons per million living (R.G.'s figures for 1920). Dr. Perkins outlined the main predisposing causes—trade and occupation, climate, local pathological conditions especially in the upper respiratory tract, general constitutional factors. There was a distinction between recurrent bronchial catarrh and a single acute attack of bronchitis, which latter may occur without special predisposing conditions, and for which ordinary drugs were useful and vaccines truly curative. When catarrh is constant vaccines were more efficacious in relieving such symptoms as cough or spasm than in curing. Chronic bronchitis was usually secondary to some chronic pre-existing disease, especially of the upper respiratory tract, from which infection of the bronchi by inhalation could easily take place, and the eradication of this underlying condition was essential to the successful treatment of the bronchi. In other cases metabolic conditions were predisposing factors—obesity, overfeeding, and alcoholic excess. Treatment should be continued until a satisfactory convalescence was secured. The open-air habit of life should be preserved or restored and a good plan for the bronchitic was to take his annual holiday in the winter at a place where outdoor exercise is pleasant. The conditions of life in office and home could be improved and heated stuffy atmospheres abolished. A valuable adjunct was respiratory exercises such as those systematised by Mr. C. MacMahon at St. Bartholomew's Hospital, the object of which is to restore and increase the movement of the lungs.

While not undervaluing our present methods of treatment, Dr. Perkins suggested, in conclusion, that important predisposing conditions were often present, the treatment of which was essential; that medicinal measures did not cover the whole ground; that it was important by pure air and exercises to increase the functional activity of the lungs. By removing foci of infection much could be done to prevent catarrh. After an attack much could be done to defend the patient from becoming a chronic bronchitic by enjoining the value of fresh air and exercise of the lung.

Dr. Symes discussed the bacteriology and vaccine treatment of chronic bronchitis. In the infective varieties reports were universally favourable; cases were never made worse. He was opposed to the use of stock vaccine, and mixed infection being the rule an autogenous vaccine was highly desirable. The exciting organisms were constantly present in the nose and may be isolated by means of a nasal swab when sputum cannot be satisfactorily obtained. The dose must be sufficient to excite a reaction and repeated every five to seven days. In the interval between attacks stock prophylactic vaccine might be given.

Dr. Michael Foster (Harrogate) described climatic treatment abroad. The first question was, Can the disease be arrested? Too little consideration had been given to these early cases drifting into lifelong bronchitis, and in these early cases climatic treatment enables habits of coddling to be set aside. Dry air lessens secretion and the diminished air pressure of the Alps dilates the alveoli gently and may be of great value in the winter in early cases; insomnia is generally aggravated by high altitude and the chest wall must not be rigid. Spa treatment afforded another useful method of benefiting early cases. When bronchitis was firmly established the treatment must aim at diminishing secretion—warmth, absence of fog, and dry air, though some are helped by a moist climate when cough was hard and sputa scanty. The Western Riviera was drier than the Eastern; patients with scanty expectoration were probably better off at Rapallo than further East. Egypt is ideal for certain months for cases with profuse expectoration;

asthma cases should not be at sea-level; as small an elevation as 100 ft. might make all the difference as to frequency of paroxysms.

Mr. G. Seccombe Hett (London) said that all the cases of chronic bronchitis which he saw were descending infections from the upper respiratory tract. Children with bronchitis usually have a poor air way through the nose and infected tonsils and adenoids. Deflected septum induced nasal catarrh and nasal sepsis. Undue patency of the nose also induced nasal sepsis and a descending infection. Tonsillar infection in adults was less likely to produce bronchitis than nasal infection, but infected teeth should always be removed. Chronic bronchitis was very apt to follow asthma and hay fever because swelling and hypersecretion in the upper respiratory tracts sooner or later allows of infection. Removal of polypi, not in themselves the cause, might relieve bronchitis and asthma by promoting drainage of infected ethmoidal cells.

Dr. A. C. Inman (London) said that every case of chronic bronchitis should have the sputum examined for tubercle bacilli, and the possibility of a syphilitic infection must always be borne in mind. From a bacteriological point of view the most important organisms were streptococci and *B. friedländer*. In the treatment of the latter infection vaccine was very useful, in the former disappointing. Preventive inoculation should be carried out during periods free from catarrh.

Prof. E. L. Collis (Cardiff) wrote that chronic bronchitis contributed so much to sickness and death that it was facile princeps amongst disease, especially in later life. It was probably responsible annually for 80,000 years of invalidity and 28,000 deaths. The death-rate has been falling rapidly since 1870. The disease is induced by wintry weather and atmospheric pollution: a chronic traumatic origin was commoner than an infective. Reduction in morbidity and mortality may be expected to follow (*a*) such social uplift as increases the health of lower grades of society, and (*b*) smoke abatement in industrial districts and great towns.

Dr. F. G. Layton said the belief in magic was not yet dead; he had recently come across a boy suffering from pulmonary disease who had a sheep's lung tied to each foot.

Dr. Florence Stoney (Bournemouth) drew attention to dental sepsis as a cause of chronic bronchitis.

Dr. Aston Key (Portsmouth) said that one of the great troubles was that the bronchial mucosa was incapable of repair. It was true that many cases of bronchitis arise from obstruction to the nose, and such always succumbed to bronchitis whether the nose were operated upon or not.

Dr. G. B. Batten (Dulwich) gave his experience during 37 years of general practice. In the old days chronic winter bronchitis was very common and difficult to treat, the old ladies being overdressed and living in stuffy atmospheres. The introduction of the fresh air treatment of tuberculosis was a great help and these patients were weaned from stuffy rooms and overclothing to fresh air habits, and he now knew of no individual who had habitual winter bronchitis. The important thing is to make the patient live out of doors.

Dr. Hyla Greves (Bournemouth) said chronic bronchitis was usually a secondary infection rather than a primary one, and constitutional disorders such as gout, arterio-sclerosis, renal disease, and peribronchial tubercle were common underlying factors. In treatment climate plays an important part, and the south of England provided many suitable resorts. The resistance to cold should be gradually cultivated. In acute and subacute cases dry cupping of the bases of the lungs was a valuable agent.

Sir Thomas Horder stressed the importance of such underlying constitutional disorders as gout, hyperpiesis, myxœdema, and other endocrine disorders. All cases of bronchitis were not infective; in some infection plays but a minor part, and this explained the success of vaccine in one class and its failure in another. Cases of "mucous diathesis" whether involving the respiratory or alimentary tracts were very difficult to treat. Mucous bronchitis was intermediate between the paroxysmal type (asthma) and the true infective types. It was very important to treat the nervous cardiovascular and digestive systems in such patients.

Dr. Donald Hall (Brighton) said that he had found autogenous vaccine of value and had had a very mixed experience of operative treatment in the upper respiratory tracts.

Dr. Perkins, in reply, said that he was satisfied with the result of the discussion. The fact that chronic bronchitis was usually secondary had emerged and the importance of educating people to an open-air life was well recognised.

SECTION OF LARYNGOLOGY AND OTOLOGY.

THURSDAY, JULY 26TH.

This combined section met on two days under the presidency of Mr. E. B. Waggett. In opening a discussion on

Internal Ear Deafness

Dr. Dan McKenzie (London) began by deploring the disparity between our anatomical as opposed to our pathological knowledge of the labyrinth. He described the well-known difficulty of assessing the value of tuning-fork tests in deciding whether the case was of middle or inner ear deafness. With regard to obstructive deafness, nobody had thrown doubt upon the correctness of the inferences to be drawn; but he described a case in which all the classical science of nerve deafness were present in which removal of impacted cerumen was followed by immediate cure of the deafness. Mixed deafness was the commonest type of all, and the affection of the labyrinth in these cases might be merely a functional derangement. The commonest cause of nerve deafness was middle-ear disease; this was a fundamental point and based on statistics from his own practice. The prognosis of nerve deafness with middle-ear disease was grave unless the latter could be arrested. Myxœdematous deafness was a mixed type but happily yielded readily to thyroid medication if begun early. He next dwelt upon the relation between the vestibular reflexes and nerve deafness; they co-existed in acute labyrinthitis, though rarely in a chronic labyrinthitis. He had not seen vertigo in the sudden deafness that occurs in mumps. Vertigo might attend upon almost any type of disease, whereas tinnitus was usually tympanic. Having dealt with noise-deafness, senile deafness, syphilitic and toxic deafness, he concluded by sounding a note of hope provided that means could be found for encouraging pathological research of the type so well exemplified in J. S. Fraser's work.

Thirteen speakers took part in the discussion. Mr. W. M. Mollison (London) grouped deafness into qualitative and quantitative. In the qualitative types, obstructive or perceptive, there was a loss either of the upper or lower tones, whereas the remainder of the scale was unaffected. In quantitative ear trouble there was an alteration all along the line; some of the quantitative cases were familial, some toxic, and some due to depression or elevation of sensitivity. Unlike the opener, he had seen vertigo with the sudden deafness of mumps. He mentioned the relation between Paget's disease and nerve deafness, and gave notes and radiograms of a case. He dwelt upon the importance of the lowering of the upper tone limit in diagnosing between middle and internal ear deafness, and of the use of the monochord both by air and bone conduction. He described cases of astounding acuity of hearing in the blind and in certain types of neurasthenics, where whispers could be heard round several corners. Similarly, hypersensitivity of the canals was a clinical entity. Perhaps the canals were getting less valuable to man, and this hyperacuity in neurasthenics was a want of progress in the acquired art of excluding unwanted stimuli. Mr. A. J. M. Wright (Bristol) classified 71 cases from the point of view of ætiology;

ose with an obvious cause, such as trauma and philis, offered no difficulty. He had seen dramatic provement with salvarsan given early. Of the mainder two-thirds were females. In these doubtful ses septic foci accounted for a certain number; me were functional, and in these one could usually d a history of some suggestion early in the case. the remainder, childbirth, thyroid deficiency, and so-motor rhinitis accounted for the majority. He as satisfied that with regard to the deafness due to rve traumatism by noise, removal of the cause led an arrest of the progress of the lesion. Sir J. UNDAS-GRANT, with a facility which can result only om a vast experience, touched rapidly upon a wide nge of subjects, among them senile deafness (which, e other senile changes, was not a question of ronology), the explanation of the value of quinine unilateral labyrinthine vertigo, the value of tuning-rk tests, the question of the effect of pre-existing r disease in war cases, the use of perchloride of ercury in auditory nerve traumatism, deaf-mutism, d his instrument for the cold air caloric test. Mr. . J. LEIGHTON (Manchester) said syphilis was not to overlooked. He emphasised the psychological ctor both in ætiology and treatment of deafness, scribed a labyrinthine storm relieved by inflation, d mentioned the importance of caloric tests in stinguishing between central and labyrinthine lesion.

The PRESIDENT said the speeches had brought out e important point that in a large proportion of ternal ear deafness cases evidence of middle-ear sease was present. Many cases of so-called nerve afness were possibly due to disease in the foramen tundum. It was important, and perhaps significant, at all cases of hyperostosis of the meatus showed ns of deafness of the internal-ear type. He d not found during three years with an army soaked with quinine" any chronic deafness caused quinine or by malaria, and he had some doubt to the existence of deafness due purely to such uses.

A concise and workmanlike paper was read by Mr. D. D. DAVIS (London) upon

Retrobulbar Neuritis of Nasal Origin.

tabulated 54 carefully worked out cases, in four ly of which he had been able to prove the existence sinusitis. In these there was gross evidence of the uble, and he deprecated any attack upon the sinuses the absence of very definite signs of suppuration. e neuritis was wont to wax and wane with or without atment, which made it difficult to accept accounts cures. Sir STCLAIR THOMSON (London) agreed with . Davis, and condemned a tendency in some untries to operate upon sinuses without evidence of ease, simply because improvement had followed such ps on occasion. Progress in surgery must be on er foundations than this. Dr. RITCHIE RODGER ull) and Mr. SOMERVILLE HASTINGS (London), the other hand, had seen dramatic improve-nt after opening sinuses apparently healthy, d ascribed a larger proportion of cases to sinus uble.

The morning ended with an interesting paper by . H. D. GILLIES (London) on the

Surgical Treatment of Nasal Deformity

h special reference to the nose of tertiary syphilis. s lantern slides bore convincing testimony to the vance he has made in this field, by the introduction a two-stage operation. The first stage consists in intranasal incision of the scar which anchors the aining nose to the pyriform opening. This release bles the nose to be pulled down into a normal sition, the resulting large raw area on its deep face giving a measure of the loss of lining that has urred. The replacement of this loss by Thiersch ft is achieved by his modification of the Esser inlay, l permits the second stage—of cartilage grafting—lly to rid the patient of the "syphilitic" appear-e. In a depressed fracture the cartilage graft may inserted without the preliminary stage.

The afternoon was pleasantly spent in a visit to the Portsmouth Eye and Ear Hospital, where Mr. C. A. SCOTT RIDOUT showed a series of cases.

FRIDAY, JULY 27TH.

In opening a discussion on

Spasm of the Larynx,

Sir STCLAIR THOMSON, after a definition of terms, briefly reviewed the anatomy and physiology of the parts concerned and began by classifying the known causes of spasm. He emphasised throughout the importance of psychological factor in intensifying and even originating spasm, and mentioned that in his long experience he had not had occasion to perform tracheotomy, though he was far from condemning the procedure where the strain on the heart was obviously too great. He was convinced that whooping-cough in adults sometimes was the cause of spasm (an original observation this) and quoted cases due to gout, morphia-habit, and tabes. Like most of his hearers, he had found difficulty on occasion in distinguishing between abductor paresis and adductor spasm, but was able to indicate clinical methods of solving the difficulty. Having touched upon Semon's law and spasm in anæsthesia, laryngismus stridulus, hiccough, and epilepsy, he concluded by summing up the lines of treatment at our disposal. The problem, as ever, depends upon diagnosis, and in each case a most exhaustive examination was necessary to ensure that we were not treating a case of paresis by sedative methods.

Sir J. DUNDAS-GRANT drew a very definite distinction between laryngismus stridulus and laryngitis stridulosa, the latter condition being the same as croup and being found in rickety children. Perhaps the deficiency of calcium led to a relative hyper-excitability of the nervous system, and such irritations as adenoids supplied the necessary stimulus. He discussed the laryngeal crisis of tabes and their relief by local anæsthetisation of the larynx. He described laryngeal vertigo, and an explanation of it, and concluded by describing the relief of functional ephonia by faradising the lingual tonsil. Dr. W. J. KELSON (London) said that we must not neglect the fact that the ventricular bands form a false glottis which at times becomes spasmodically closed. He discussed the difficulty of distinguishing between spasm of the adductors and paresis of the abductors. He pointed out that the muscles which close the air-way happen to be stronger than those which open it, and, therefore, the tendency of any nerve irritation is to cause closure. The excitability of the reflex mechanism is greater in children, and especially in sleep, when the cortical centres are depressed. He quoted two cases of fatal spasm of the glottis in children in which a necropsy revealed the signs of rickets only. He described a case of hysterical and prolonged spasm in an adult woman accompanied by a high-pitched stridor both on inspiration and expiration, which was treated by galvanism. Dr. PETER MACDONALD had had unique opportunity of observing intimately a case of recurrent glottic spasm in a woman, and described the means regularly employed to bring an attack to an end. The PRESIDENT, unlike the opener, had had occasion to perform tracheotomy for glottic spasm upon a patient suffering from an aneurysm, and mentioned the danger of delaying intervention too long. Dr. WILLIAM HILL (London) described a dramatic case in which the patient had died as he made the incision for tracheotomy, and discussed the occasional need for artificial respiration after tracheotomy alone had been unsuccessful. Mr. A. J. WRIGHT and Mr. S. HASTINGS also described their experience of the condition.

Mr. LEIGHTON read an interesting paper on

Organotherapy in Ear, Nose, and Throat Work.

There were many conditions in which organotherapy formed a useful adjuvant to other treatment, but it was difficult to lay down rules. He might say, however, that the endocrine organs might act from excess or deficiency of secretion or from perverted secretion.

He mentioned McCarrison's work on the relation between sepsis in the tonsil and other organs and thyroid activity, and quoted cases bearing on it. The pituitary had become increasingly important, and headaches due to a derangement of the pituitary had to be diagnosed from sphenoidal disease. Diabetes, abnormal blood pressure, climacteric deafness, neuroses, hypothyroidism were all common causes of ear trouble and were alike amenable to organotherapy. Mr. **HASTINGS** inquired as to the dosage of thyroid extract advocated by the speaker.

Short Papers.

Mr. J. A. **GIBB** (Maidstone) read a short paper upon the Referred Pain of Nasal Sinus Disease. The position to which pain is referred was often disregarded. He would tell us of some cases in which a study of referred pain had been useful in his experience. Other viscera sometimes chose the same areas as did the nasal sinuses, and therefore, of course, one's observation should be backed by a thorough general overhaul. The position of the pain did not always depend on the severity of sinusitis, but might alter slightly if several sinuses were involved. He detailed the areas for the various sinuses and gave cases illustrative of his thesis. Mr. **WRIGHT**, Mr. E. M. **WOODMAN** (Birmingham), and Mr. T. B. **JOBSON** gave cases from their own experience.

In the afternoon Mr. V. E. **NEGUS** (London) read a paper upon a Newly-described Function of the Vocal Cords. The voices of animals did not necessarily depend on the size of their cords. During independent use of the fore-limbs for such actions as hanging from a branch or bringing them together against resistance the thoracic wall must be brought to rest to give a fixed origin to the muscles attaching the limbs to it. The pressure changes in the thorax are so great that sphincteric muscular action is inadequate to control them, and *valvular* action is brought into play in the larynx. He suggested that the cords closed and that the diaphragm descended a little, leading to a reduced pressure which played an important part in fixing the thorax. He used facts from comparative anatomy in support of his argument, but was inclined to infer too much from the observations made, and to underrate the many other causes which have operated in evolving the present structure of the larynx in man and other animals. His paper was discussed by the **PRESIDENT**, Sir **STCLAIR THOMSON**, Sir J. **DUNDAS-GRANT**, Mr. **JOBSON**, Mr. **WRIGHT**, and Mr. **RIDOUT**.

Sir J. **DUNDAS-GRANT** read a short paper upon Canfield's Operation upon the Maxillary Antrum, with cases. The method, described in 1908, consists essentially in a preturbinal approach to the sinus, the edge of the pyriform opening being removed subperiosteally until an inspection can be made of the interior. In the original operation, an elaborate flap of mucosa is prepared during the removal of the anterior third of the inferior turbinated bone, with which to line the antronasal communication, but the speaker agreed with Skillern and others in finding this unnecessary. The operation seems one to be reserved for those infrequent cases in which simple infra-turbinal drainage and lavage fail after some weeks to effect a cure. The **PRESIDENT**, Mr. **HASTINGS**, and Mr. **WRIGHT** voiced the general attitude of the audience with regard to leaving plugging in the nose, and it was left to Dr. W. **HILL**, ever the champion of the under-dog, to side with the reader of the paper as to its occasional necessity.

Dr. W. **HILL** read a paper upon Butyn as a Local Anæsthetic in nose and throat work. He had found it capable of replacing cocaine in some cases though not in all. It was two and a half times as expensive and was found to be less reliable in some 60 cases. Sir J. **DUNDAS-GRANT**, Dr. **SHEEHAN**, and the **PRESIDENT** also spoke.

After the last paper Dr. **EASTMAN SHEEHAN** (New York Post-Graduate Hospital) gave a novel demonstration of animated photographs of plastic operations for the relief of deformities of the nose.

DISEASES OF CHILDREN.

THURSDAY, JULY 26TH.

THIS section met on two days. At the first session the President, Dr. **EDMUND CAUTLEY** (London), being in the chair, a discussion on

Acidosis and Alkalosis in Children

was opened by Dr. P. J. **CAMMIDGE** (London), who said that the old idea of acidosis, in the sense that the symptoms associated with it were dependent upon the presence of unneutralised acid products of abnormal metabolism in the blood, had had to be replaced by a new conception. The normal faintly alkaline reaction of the blood was maintained constant by buffer substances which could deal with a large quantity of acids or alkalies without the reaction of the fluid being altered. The entrance of acid products into the circulation decomposed some of the bicarbonates and produced a relative excess of carbon dioxide which was then excreted by the lungs. Normally the bicarbonate was quickly replaced, but under pathological conditions the alkaline reserves might be depleted and the proportion of bicarbonate permanently diminished. Such symptoms as air-hunger would ensue, and finally death. Acidosis then, was a condition in which the concentration of bicarbonate in the blood was reduced below the normal level. Theoretically acidosis might arise by introduction from without of a large quantity of mineral acid, by abnormal formation of acids within the organism (diabetic coma), defective elimination of excretory products (interstitial nephritis), or by excessive drain of bases as in profuse diarrhœa. Alkalosis would occur with excessive intake of alkaline bases. A similar condition might arise should there be an abnormally small amount of acid formed in the metabolic cycle, but of this there was no convincing example. An increase in the alkaline reserve occurred during gastric digestion when acid was excreted into the stomach. Finally it could be brought about by excessive elimination of CO_2 as in voluntary forced breathing. The speaker illustrated his points by reference to cases of diabetes and cyclic vomiting in children.

Dr. **RUTH CONWAY VERNEY** (Edinburgh) read a paper on the reaction of the blood in children. By observing the hydrogen-ion concentration in relation to the tension of free and of combined CO_2 it was possible to get some idea of the factors controlling the acid-base balance. Among these factors the blood-buffering power was of great importance. She wished to emphasise the value of protein base salts as buffers. Of these hæmoglobin compounds were the chief. She explained the way in which this buffering action of hæmoglobin was brought about. The results which she had obtained by blood estimations in normal children and in those with anæmia confirmed this. She had also studied the blood of children with post-operative acidosis. She hoped to build up a method by which a prognosis could be given as to the likelihood of acidosis occurring in a child about to undergo operation.

The **PRESIDENT** said that there was still a certain confusion in his mind as to the differentiation and effects of acidosis and alkalosis. Could ketonuria occur without acidæmia? If it could exist with alkalæmia, as some speakers had observed, it implied that imperfectly desaturated fatty acids were circulating in a blood in which there was an excess of alkaline bases.

Dr. E. P. **POULTON** (London) had listened with admiration to Dr. Cammidge's exposition of a difficult subject, but he did not agree with him on certain points. Although three years ago the speaker had himself suggested the classification used by Dr. Cammidge he now preferred to do away with the terms acidosis and alkalosis, and substitute "acidæmia" and "alkalæmia" for an increased or diminished hydrogen-ion concentration in the blood. He protested against the theory first put forward by Pavy, and revived by Dr. Cammidge, that coma was due an inability of the blood to transport CO_2 from the ues. Dr. Poulton spoke of the association of alæmia with tetany and described that form of any which is brought about by forced breathing. ssibly it was not the alkalæmia itself but some ration in the balance of metallic ions which ught on the condition. He mentioned a case t had tetany from a gastro-colic fistula through ich valuable HCl was passed in the stools. Cure owed the closing of the fistula. J. S. Haldane shown that the ingestion of large doses of monium and calcium chloride caused an increase ixed acid in the blood. This explained the success these drugs in the treatment of tetany. In two es of acute rickets at Guy's, Osman and Bayers found a marked fall in the plasma bicarbonate. considered, however, that diminished plasma arbonate was an accompaniment and not the se of rickets.

r. **ERIC PRITCHARD** (London) agreed that the w that acidosis and ketosis were the same obscured real significance of acidosis. Health in children ended more on the extent of the alkaline reserve n on any other factor. The fæces were a very ortant source of elimination of metabolic pro- ts. Where the stools contained much fat, as in ets, bases were excreted in combination with y acids and the alkaline reserve was thus rapidly leted. The fatty acids in the fæces might be due unabsorbed fat, or they might be produced in the od, neutralised, and then excreted by the intestine. ective oxidation was one of the causes of the earance of fat in the fæces and of depletion of the aline reserve. It was usually due to overfeeding to absence of fresh air and sunlight.

r. **CATHERINE CHISHOLM** (Manchester) said that her experience acidosis occurred frequently in umonia, and the disease often responded quickly arge doses of alkalies.

r. **CAMMIDGE** briefly replied.

olonel R. J. **BLACKHAM**, R.A.M.C. (retd.), read a er on

Cows' Milk in Infant Feeding.

fortunately, he said, breast-feeding was not always sible and then cows' milk was the most practical stitute. The best form in which to give cow's k was, however, a matter on which there was siderable difference of opinion. Raw milk was ocated by some, but it was dangerous on account the bacteriological infection it could engender. casein of one animal was, to an appreciable ent, toxic to the offspring of another animal. t caused an albumin to lose its individual characstics and thereby diminished its toxic action. He orsed Prof. Marfan's saying: "Cows' milk is ter raw than cooked for calves and better cooked n raw for infants." He discussed the advantages med for condensed and dried milks. In his erience infants reared on the former were fat, , and often listless. Milk dried by the spray hod had the advantage that it formed a curd that of human milk. It was constant in comition, contained most of the vitamins, and was not le to contamination.

FRIDAY, JULY 27TH.

Summer Diarrhœa.

r. **DAVID NABARRO** (London) opened the discus- . He gave a review of the work done by bacterio- sts, and of his own observations in the cases which ad studied with Dr. D. H. Paterson in 1921. In ry epidemic the organisms found had been very able. Even when the same bacillus was isolated a group of cases, its characters were apt to nge, and many subgroups were identified. Some teria, such as Morgan's No. 1 bacillus, were ittedly present in a large percentage of the cases, they were also present in the fæces of normal dren. It was impossible to assign any one of n as the cause of the disease. In America entery bacilli had been isolated in a number of cases which clinically showed blood and mucus in the stools. Similar cases had also been recorded in England, but in this country they formed a very small minority. He had therefore come to the conclusion that summer diarrhœa was not an infective disease in the strict sense of the word. The primary cause was not bacteriological but nutritional. He agreed with the dictum of Pfaundler that the children sicken "ex alimentatione," and that they died "ex infectione." Exposure to heat or cold, bad air, over-clothing, and improper feeding paved the way for bacterial infection. At the same time there was probably an increased virulence of the organisms concerned. The incidence of summer diarrhœa had decreased considerably of late years, and he hoped that the disease might soon become a thing of the past. The work of welfare centres in teaching mothers how to clothe and feed their children, the reduction of flies in cities, and the use of dried milk were all contributing towards this end.

The **PRESIDENT** said that Dr. Nabarro had raised many interesting points. He himself thought that summer diarrhœa was infective. In his hospital, although the cases were nursed like typhoid, the disease sometimes spread in a ward from one child to another. The infection in these instances was probably carried by flies. Some of the most severe toxæmic cases he had seen had begun in well-nourished children. In them a predisposing state of nutrition did not appear to have had anything to do with it. He considered that the disease was infective, but that many different organisms were involved.

Dr. D. H. **PATERSON** (London) pointed out that true summer diarrhœa occurred in only a small proportion of children who had diarrhœa in summer. The Americans distinguished between fermentative and infective diarrhœa according as to whether the stools contained blood and mucus or not. In his series at Great Ormond-street, out of 149 only four had shown blood and mucus. Fifty per cent. had a history of dyspepsia, the other half were fat and over-fed. In such children a spell of hot weather might bring on an acute intestinal upset. If they were taken off food altogether, acidosis was likely to supervene. Most of the cases of diarrhœa were due to bad feeding and mismanagement. Only a small minority were the result of a specific organism. In proof of this he maintained that a diet in which fermentation was reduced to a minimum was the most successful in treatment.

Dr. **BERNARD MYERS** (London) followed Finkelstein's classification of nutritional disorders. Excess of sugar and fat was a common cause of intestinal fermentation. Treatment in these cases consisted in reducing the sugar and the fat in the food. Protein was well tolerated. Some cases were nutritional, some infective; the treatment of the two conditions was different.

Dr. **CHISHOLM** supported the infective theory. The decline of the disease was due to welfare work and to the care taken in cities to prevent the spread of infection.

Dr. E. P. **BAUMANN** (Johannesburg) said that we had hitherto made a mistake in considering that all cases were infective. Some had a nutritional basis. We must not, however, go to the other extreme. The mode of onset would differentiate between the two types. Finkelstein fed his cases on buttermilk or whey; he seldom starved, never for more than six hours. Buttermilk had the advantage of being a food rich in water and salts.

Dr. G. B. **SWEET** (New Zealand) said that he believed in Dr. Finkelstein's treatment, but protein milk was difficult to prescribe in general practice. He had obtained considerable success in treatment of cases with dried skim-milk. It was simple to use, free from germs, and contained very little fat. It was the fat in the food which was the chief source of trouble.

Dr. **PRITCHARD** laid stress on the reaction of the fæces as a guide to treatment. In fermentative diarrhœa the stools were acid, when there was proteolytic decomposition they were alkaline. Buttermilk was merely a coarse method of introducing the lactic acid bacillus. He preferred to give lactose with lactic acid bacilli when the stools were alkaline, and protein milk when there was acid fermentation. Indiscriminate treatment with protein or sugar solution was equally unsatisfactory. Instead of buttermilk he used a solution of pure casein. Saline was preferable to whey when salts were required. He agreed with the majority of speakers that cases might be nutritional or infective. Children who had been fed on carbohydrates suffered most in an epidemic.

Dr. NABARRO and Dr. PATERSON replied to the discussion.

Dr. HUGH ASHBY read a paper on the

After-Results of Abdominal Tuberculosis in Children.

He laid stress on the difficulty of arriving at a certain diagnosis. It was important to exclude cases of rickets or dyspepsia which might closely resemble tuberculosis. Resistance to tuberculosis in early life was at its minimum. Cases under 1 year were practically always fatal, but the prognosis improved with the age of the child. The disease was most common at the age of 3 years. The source of infection had been a matter of considerable dispute. It had been stated that in 50 per cent. the disease was bovine, but in his opinion the majority of cases were due to human infection. With regard to the after-results in a series of 250 cases which he had been able to follow up, 56 per cent. were cured, 8 per cent. were doubtful, and 36 per cent. had died. These statistics showed the seriousness of the disease in children. In the cases which had recovered the large majority had grown up and kept perfectly well, a few had a tendency to colic and to looseness of the bowels. In some a mass of calcified glands could be felt in the same situation as the former enlarged glands, but they caused no trouble.

Dr. E. A. COCKAYNE (London) commented on the absence of after-effects. He also had felt calcified nodules which produced no symptoms.

Dr. PRITCHARD did not agree that abdominal tuberculosis under 1 year of age was invariably fatal. During the last ten years he had treated a number of children who had been infected by tuberculous mothers. Early diagnosis was made by means of tuberculin injections. In his series there had only been one death. Treatment by tuberculin had been very successful.

Dr. SWEET had obtained very good results in his cases by tuberculin treatment.

Dr. E. S. MOLYNEUX (Leamington) read a paper on the treatment of tuberculous cervical adenitis by radium. The treatment was painless and safe provided the technique was carefully carried out, and he had obtained a cure in nearly every case. Recurrence was rare. Caseating masses of glands, suppuration, and the presence of old sinuses were no bar to treatment. No scar was left unless suppuration had already occurred.

EXHIBITION OF INSTRUMENTS, DRUGS, FOODS, AND APPLIANCES.

(*Concluded from p. 306.*)

FOOD PREPARATIONS.

Foodstuffs and food accessories were represented by a large number of separate exhibits. [4] Bantam Products Ltd. (Farnley, Leeds): showed a preparation consisting of the soluble portion only of the coffee beans, the woody fibre having been removed; by this means a cup of fresh coffee of any desired strength can be instantly prepared with hot water alone, a 1*s.* 6*d.* tin providing 36 ordinary cupsfull.—[10] Food Products Ltd. (11, Queen Victoria-street, London, E.C. 4): a series of bovo-lactin foods, devised and elaborated by the late Dr. E. C. Hort, consisting of calculated amounts of animal protein, hæmoglobin, milk solids, and carbohydrates. Bovo lactin essence contains, per cent., protein 30·4, fat 0·2 ash 18·8, moisture 23·3, carbohydrates and extractive 27·4.—[46] Bovril Ltd. (148, Old-street, London E.C. 1): meat extract containing fibrin and albumin in concentrated form, with a special invalid preparation more highly concentrated and devoid of seasoning Attention was directed to the giving of half a pint o bovril before administration of an anæsthetic for the avoidance of post-operative sickness.—[49] Cadbury Bros., Ltd. (Bournville, Birmingham): an exhibit o Bournville cocoa and Bournville chocolate conforming to the highest standards of purity and uniformity.—[27] Food Education Society (329, Vauxhall Bridge-road, London, S.W. 1): a selection of literature, non-dogmatic and philanthropic, to educate the public in matters of food, cookery, and health; leaflets on diet for brain workers, aids to fitness, the importance of fat, how to choose sugar and others.—[53] Wm. Gaymer and Son, Ltd. (Attleborough, Norfolk) various brands of Gaymer's cyder, including the quality known as "dry," prepared from Norfolk apples.—[75] Glaxo (J. Nathan and Co., Ltd., 56, Osnaburgh-street, London, N.W. 1): full-cream, three-quarter-cream, and half-cream standardised dry milks for infants and adults, the milk being dried by a process proved to be non-destructive of the accessory food factors; attention was called to the timely use of glaxo in hot weather as a prophylactic against epidemic gastro-enteritis.—[50] Mead, Johnson and Co. (40, Lexington-street, London, N.W. 1): dextrines and maltose combined with cows' milk and water to form a complete diet for infants. No feeding directions accompany the packages, the doctor being left free to regulate the diet according to individual need.—[59] Horlick's Malted Milk Co. (Slough): an easily digested and highly nutritious diet for invalids and convalescents and a complete food for infants, filling a special need in Red Cross work, for preparation requires no cooking, the powder being simply briskly stirred into hot or cold water. Tablets are also available.—[76] Oxo Limited (Thames House, London, E.C. 4): Oxo fluid beef, being a concentrated form of stimulating extractives; Hospital-Oxo for invalids, peptonised and unseasoned; Lemco pure unseasoned beef extract; and the well-known Fray Bentos food products.—[16] Prideaux's Pure Casein Co., Ltd. (16, Southwark-street, London): the Dorsella milk food for babies and nursing mothers, a full-cream dried milk powder, prepared under approved conditions in Dorset. One pound cartons are supplied in bulk to welfare centres at 1*s.* 6*d.* in winter, 1*s.* 3*d.* in summer; also "casumen" pure milk casein containing 93 per cent. protein, and whey and buttermilk powders.—[84] Stowers (58, Bancroft-road, London, E. 1): cordials prepared from Jamaican and Dominican cultivated limes and from pure lemon juice with addition of cane sugar only, attention being called to the presence of vitamin A and the value of such preparations as antiscorbutics.—[22] Thew, Hooker and Gilbey, Ltd. (Buckingham): various milk products, including Hooker's malted milk and Hooker's malted milk tablets.—[37] Trufood Ltd. (Lever House, Blackfriars, London, E.C. 4): full-cream dried milk, prepared at the Creameries, Wrenbury, Cheshire, and readily reconstituted in cold water; also Humanised Trufood, with part of the casein withdrawn and cream and lactose added; also Secway, a sweet whey in powder form.—[73] Virol Limited (148, Old-street, London, E.C. 1): a preparation rich in marrow and beef fats, containing malt extract, eggs, and lemon syrup, for use in cases of wasting, rickets, and malnutrition; virolised milk is held to promote sound and natural sleep. Also virolax, containing 60 per cent. liquid paraffin in finely divided form acceptable to children and adults.—[39] Vitmar, Ltd. (Callard's Vitamin Foods, 74, Regent-street, London, W. 1): a food adjunct of high caloric value and containing vitamins A, B, and C, recommended for infants and growing children as well as a galactogogue for nursing mothers.

MEDICINAL AND MINERAL WATERS.

[15] The Apollinaris Co., Ltd. (4, Stratford-place, ondon, W. 1): Apollinaris, the pure natural sparkling ineral water bottled with it own CO_2 gas; Apenta, natural aperient water for cases of habitual contipation and biliousness; Vittel, a diuretic mineral ater for the arthritic and gouty.—[80] Bath (Mr. ohn Hatton, Director of Baths): an exhibit sent by he corporation, consisting of photographs of the athing establishments and the chief features of nterest at this inland spa.—[71] Buxton (Mr. H. L. B. itt, General Manager): an exhibit of official handooks and of the waters for sale in bottle form from his mountain spa, 1000 feet above sea-level.—79] Droitwich (Mr. J. H. Hollyer, Director of Bathing stablishments): setting out the characteristics of e climate in summer and winter of England's brine-aths spa, the character of the waters, and of the ttractions offered.—[72] Harrogate (Mr. F. J. C. roome, General Manager): unique in its diversity of prings, with 87 waters of various characteristics ollected under chemical and physical control.—0] Ingram and Royle, Ltd. (45, Belvedere-road, ondon, S.E. 1): samples of imported natural mineral aters, salts, and pastilles, including Vichy-Célestins, ontrexéville-Pavillon, Evian-Cachat, Hunyadi-János, nd 20 others.

MICROSCOPES AND SCIENTIFIC APPARATUS.

[1] J. W. Atha and Co. (8, Southampton-row, ondon, W.C. 1): showed Zeiss microscopes, with cessories including the photographic ocular "Phoku" ith continuous vision, and an apochromatic objective X" for dark-ground work. [7] C. Baker (244, igh Holborn, London, W.C. 1): various types of icroscope from the R.M.S. designed for the highest search work and photomicrography down to the dvanced Student's Microscope; also Greenough's nocular and universal models.—[8] Chas. Hearson d Co., Ltd. (14, Princes-street, London, W. 1): large selection of bacteriological, pathological, ysiological, botanical, and chemical apparatus, cluding Dreyer's new fat-extraction bath for bercle antigens.—[35] Kodak, Limited (Kingsway, ondon, W.C. 2): some interesting results of the astman panchromatic film which differentiates tween yellows and reds and admits of any degree of ntrast when used in conjunction with a Wratten ter; also developing tank outfits and dark-room cessories for X ray work.—[61] Rayner and Keeler, td. (Kemp Town, Brighton): a variety of lenses and hthalmological instruments including the Edridge-reen lamp and card tests, and various new types of ns, such as the lenticular deep concave.—[30] Short d Mason, Ltd. (Aneroid Works, Walthamstow, ondon, E. 17): the Tycos sphygmomanometer, curate and portable, a practical instrument for termination of the diastolic, systolic, and pulse essures.—[25] The Tintometer, Limited (the Colour boratories, Salisbury): Lovibond's colour scale d tintometer for the measurement and registration the colours of gases, liquids, and solids; also Dr. rbet's radiometer for the accurate measurement of lour changes in Sabouraud pastilles.

SUNDRIES.

[57] The Cellular Clothing Co., Ltd. (72, Fore-street, ondon, E.C.): showed Aertex cellular clothing for alth and comfort, and a selection of red garments tting off actinic rays for use in the tropics.—0] Hoskins and Sewell, Ltd. (Bordesley, Birming-m): special beds and bedstead equipment for spitals, sanatoria, and open air treatment, including e patent wheeling spinal stand, the "silent night" spital mattress, and the Alton sunshade.—[51] nuk, Ltd. (Portslade, Sussex): materials and pliances employed in the preparation, initial lishing, and maintenance of flooring and other terior woodwork.

MEDICAL AGENCIES.

[32] Mr. W. S. Atkins (43, Bedford-street, London, .C. 2): agent for medical tranfers and for permanent non-cancellable sickness and accident policies specially devised for the medical profession.—[64] The Medical Insurance Agency (429, Strand, London, W.C. 2): founded in 1907 to advise medical practitioners as to contracts most suitable to their needs and to obtain for them policies on the most advantageous terms consistent with secure protection.—[21] The Medical Sickness, Annuity and Life Assurance Society, Limited (300, High Holborn, London, W.C.): founded in 1884, as a mutual society confined to members of the medical and dental professions, for insurance against sickness and accident on a permanent contract basis.

BOOKS AND OFFICE ACCESSORIES.

[18] W. H. Barrell, Ltd. (112, High-street, Portsmouth): showed a comprehensive exhibit of portophones, typewriters, loose-leaf ledgers, dictographs, and the kardex visible record system, specially recommended for clinical reference.—[77] H. R. Ellis (9, Lovell's-court, London, E.C. 4): medical, surgical, veterinary, and dental books, very complete on the side of psychology and allied subjects.—[31] The Hammond Typewriter Company, Ltd. (75, Queen Victoria-street, London, E.C. 4): the multiplex machine, capable of writing in every language or style of type and in which the turning of a knob suffices for emphasis or special announcement with italic or other type. The machine is fitted with special medical and chemical characters and miniature type for writing out small labels.—[26] H. K. Lewis and Co., Ltd. (136, Gower-street, London, W.C. 1): a classified exhibit of new books in many departments, including those of the Cambridge University Press, and a selection of medical stationery, case-books, loose-leaf ledgers, card-index systems, and rubber-stamp diagrams.—[5] Minty (36, Southampton-street, London, W.C. 2): the Oxford Varsity sectional book-cases without metal fittings or projections and both dust- and damp-proof.—[54] Oxford Medical Publications (1, Bedford-street, London, W.C. 2): a complete set of text-books and works in medical, surgical, and general science.—[24] Stanley Phillips (45, Brondesbury-road, London, N.W. 6): an eclectic selection of recent publications in every branch of medicine, surgery, and allied sciences, including year-books of general medicine, surgery, and special subjects, and Meyer's Medical Dictionary in eight languages.—[62] L. L. Waters and Co. (55, Commercial-road, Portsmouth): office furniture of British manufacture made by Messrs. Frank Corke and Co., Southsea, also the Doctor's National Insurance Panel Card Index Cabinet.—[74] John Wright and Sons, Ltd. (Bristol): an excellent selection of recent publications, including indexes of differential diagnosis, prognosis, and treatment; the Medical Annual, a year-book of treatment and practitioner's index; and the medical practitioner's card-index system for account keeping.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. D. L. Harding to be Lt.-Col., vice Lt.-Col. C. W. Mainprise (promoted).

The undermentioned Majs. retire, receiving a gratuity: C. Clarke (granted the rank of Lt.-Col.), G. Petit, and C. Ryles.

Temp. Capt. J. J. Walsh relinquishes his commn. and retains the rank of Capt.

The undermentioned Lts. are confirmed in their rank: F. C. H. Sergeant, W. L. S. Cox, and H. A. Gilkes.

TERRITORIAL ARMY.

The undermentioned relinquish their commns. and retain their rank, except where otherwise stated: Majs. E. C. M. Foster and J. Ewing; Capts. A. R. Bearn and H. Buck (granted the rank of Maj.), J. B. Macalpine, G. Stuart, and S. R. Wilson.

Capt. R. G. Michelmore (late R.A.M.C.) to be Capt.

ROYAL AIR FORCE.

G. Clark is granted a short service commission as a Flying Officer.

Correspondence.

"Audi alteram partem."

X RAYS IN EXOPHTHALMIC GOITRE.

To the Editor of THE LANCET.

SIR,—The leading article in to-day's issue of THE LANCET (p. 287), in commenting upon the two very excellent papers of Prof. G. R. Murray and Mr. A. J. Walton on the treatment of exophthalmic goitre, draws attention to the differences of opinion expressed therein as to the value of X ray applications. Mr. Walton has found their use "very unsatisfactory," and were the experience he records to be accepted as an average one I think all would agree with him. Surely, however, there must have been some flaw in the technique in the cases he has met with, where the effect of the rays appears to have been limited to scarring and burning of the skin, and in one case to actually producing a squamous carcinoma, without any changes in the gland or the periglandular tissues sufficient to be appreciated at a subsequent operation. My purpose in writing is not to advocate the X ray treatment of exophthalmic goitre, but that X rays, as applied by Dr. A. E. Barclay and Dr. J. M. W. Morison of this city, by the method described in Prof. Murray's paper, can be made to produce a very definite effect upon the gland without detrimental effect upon the skin I have no doubt whatever. The results in 100 cases[1] are to me, at any rate, fairly convincing, and in the same paper reference is made to a case of Mr. H. Stratford, shown at the West London Medico-Chirurgical Society,[2] in which radiation of the scar and the supraclavicular region for a year after removal of the breast for carcinoma induced such extensive atrophy in a previously healthy thyroid gland that the patient developed myxœdema.

My experience differs from that of Mr. Walton, who has "never found that it—i.e. X rays—makes a future operation more difficult on account of the fibrosis." I have operated upon several cases for Prof. Murray where X ray treatment had been previously applied, and have generally found that periglandular fibrosis is present, sometimes in so marked a degree as to render the freeing of the gland a much more difficult and lengthy procedure than usual. The fibrosis seems, moreover, to extend to the walls of the small arteries, so that the mouths of small vessels which would otherwise have closed automatically when torn across in separating the gland are unable to do so and bleed persistently, necessitating the application of many more ligatures than usual. By prolonging the operation and increasing the amount of handling of the gland and wound I believe that the prolonged use of X rays does increase the severity of a subsequent operation. Unless, therefore, X rays produce material benefit fairly quickly, their application should not be persisted with.—I am, Sir, yours faithfully,

Manchester, August 11th, 1923. ARTHUR H. BURGESS.

A NATIONAL PATHOLOGICAL MUSEUM.

To the Editor of THE LANCET.

SIR,—The cancer problem is now being tackled seriously by the medical profession, and appeal is being made to the general public for funds. May I earnestly urge that the histological side should be more widely and extensively studied? The histological structure of tumours varies so much that it is a matter of the greatest difficulty to follow them and keep them in mind. The great majority of specimens of malignant growths can be recognised quite easily, but there are an appreciable number which the pathologist finds the utmost difficulty in "spotting." Very early malignant growths and malignant changes occurring in a primary innocent tumour cause the greatest difficulty. In my own practice I meet with quite a large number of these cases, so what must be the tota number throughout the country ? These specimen would form valuable material for the investigation o cancer in its earliest stages and for the training o pathologists. I wish therefore again[1] to urge "th establishment of a national pathological museum, t contain examples of every disease of which example can be obtained, especially microscopic sections of th different tissues." These specimens should be full described and accompanied by clinical histories, s that pathologists might turn to them for guidance At present a pathologist is often unable to give precis information as to what course a case showing a unusual type of tumour is likely to take ; sometime he can get this information from a brother pathologist generally not. At present pathologists often hol different views as to the nature of certain tumours an their probable course, whether malignant or innocent Definite information on these points would b obtainable in the records attached to the specimens i a national museum.

If the appeal for funds results in a satisfactory response, I hope the committee already formed wil consider the allocation of a sufficient sum to, say, the Royal College of Surgeons, to inaugurate such a museum.—I am, Sir, yours faithfully,

ERNEST H. SHAW, M.R.C.P.

Camden-road, N., August 13th, 1923.

SAILORS AND VENEREAL DISEASES.

To the Editor of THE LANCET.

SIR,—With reference to the annotation on the above subject in your last issue, the National Council for Combating Venereal Diseases wishes to express its very grateful thanks to Sir John Collie for all the trouble he took in getting this Bill, drafted and promoted by it, through the House of Commons. The same Bill in the last Parliament became an agreed measure and only failed of becoming law owing to the sudden dissolution. Sir John Collie was kind enough to undertake to father it at its re-introduction in the present Parliament, and as an agreed measure it passed the House of Commons. The thanks of the Council are also due to Lord Muir Mackenzie who, at the request of Sir John Collie, undertook to shepherd it through the House of Lords. The National Council has been working to obtain this legislation since 1919.

I am, Sir, yours faithfully,

102, Dean-street, W., August 13th, 1923. E. O. GRANT, Secretary.

VILLAGE SETTLEMENTS FOR EX-SERVICE MEN.

To the Editor of THE LANCET.

SIR,—It is to be hoped that Lord Haig's appeal will not pass unheeded. It is because the majority of English men and women do not understand the position of the ex-Service man and are unable to grasp the truth that this apparent apathy exists. May I take the example of the ex-soldier consumptive, whether he be officer or private ? What can be more awful than his present position—unemployed and unemployable in the ordinary workaday world ? Yet in a village settlement such as Papworth he may not only find health but suitable employment at full wage or salary for the remainder of his days. At the moment the ex-officer has no opportunity of benefiting from such a scheme, being debarred by the regulations of the Ministry of Pensions. Health, employment, hope—all these he could obtain under the village settlement scheme. These men—both officers and men—desire the opportunity to work, to lead a life of usefulness without detriment to their health, but so far this country has given them very little help or encouragement. Capital only is required ; the men cease to be a burden to the State once they are settled in the village settlement.

I am, Sir, yours faithfully,

Cambridge, August 7th, 1923. P. C. VARRIER-JONES.

UNIVERSITY ELECTIONS IN THE NEW DAIL (IRISH FREE STATE).

To the Editor of The Lancet.

Sir,—A meeting of graduates of the National University, Ireland, adopted as candidates for the representation of the University in the new Dail Mr. Michael Hayes, M.A., Mr. John MacNeill, D.Litt., and Mr. William Magennis, M.A. A committee to secure the election of these candidates was appointed, and in the course of an appeal on behalf of the candidates has stated: Under present conditions stability of government and public security are the supreme necessity. Neither education, public health, nor any other vital service of the nation can be promoted unless stable government and respect for law are assured. Much constructive work awaits the coming Dail. Educational reform, long overdue, must be no longer delayed; no departments more urgently demand improvement than university and secondary education. Hand in hand with educational reform must come a real effort to provide efficient health services for the nation. The committee concludes by stating it confidently expects the vote and support of the electors for the three candidates selected, who share the views expressed in the appeal on their behalf by the Committee of Graduates.

The three candidates selected were the representatives of the National University in the last Dail. Although none of the candidates selected is a member of the medical profession, nevertheless it must be said all of them showed a very keen interest in medical matters in the last Dail, and were always ready to assist the medical profession whenever there was an occasion to approach the Minister of Local Government, who had charge of medical affairs. In the latter respect Mr. Hayes was frequently the means of bringing the profession in the Free State in contact with the Minister of Local Government. It was Mr. Hayes who arranged for and introduced to the Minister of Local Government the deputation from the Irish Medical Committee who waited recently in connexion with the proposed scheme of medical legislation for the Irish Free State. Mr. Magennis also did very excellent work in the last Dail for the profession. He made, on different occasions, eloquent and powerful speeches urging the better treatment of Poor-law medical officers both as regards salaries and pensions, and put himself on every occasion at the disposal of the profession when it was a case of redressing their legitimate grievances. It is hoped that medical graduates of the National University resident in Great Britain and Ireland will not fail to record promptly their votes for the candidates whom they have reason to believe will best serve medical interests and the interests of public health generally in the new Dail.

At the time of writing Dublin University has not selected its representatives for the Dail. It is, however, almost certain that Sir James Craig, M.D., will be a candidate if there is to be a contest, and it is hoped the electors of the Dublin University will record for him their first votes. Sir James Craig was a most successful and popular member of the last Dail; he did excellent work in enlightening members of that body with regard to all matters of a medical nature, and whenever, in this respect, he made representations to the Government he generally succeeded in getting most of what he wanted.

I am, Sir, yours faithfully,
T. Hennessy, F.R.C.S.I.,
Irish Medical Secretary, B.M.A.

South Frederick-street, Dublin, August 13th, 1923.

PS.—University electors should lose no time in returning their ballot papers when signed and with them the identification certificate; either without the other is useless. The poll will be open for one day only—Monday, August 27th—and as the postal service is still somewhat disorganised, the proper course is to have the necessary papers signed and returned without an hour's delay.

THE IMPERIAL CANCER RESEARCH CAMPAIGN AND THE CANCER PROBLEM.

To the Editor of The Lancet.

Sir,—Major Leonard Molloy's letter in your issue of August 11th requires correction in one or two essentials. The British Empire Cancer Campaign is distinct from the Imperial Cancer Research Fund; the latter has been in existence for 20 years. The British Empire Cancer Campaign is not yet in existence as an organisation engaged in cancer research. Dr. Molloy says that the Treasury grant to the Imperial Cancer Research Fund is "utterly inadequate." This is an erroneous statement of the case, because the Imperial Cancer Research Fund is not now and never has been in receipt of Government financial support, although several Government departments are represented on its general committees and subcommittees. Permit me to add that I disagree with the implication in Dr. Molloy's letter that the only requirement for success in cancer research is money. It is a libel on men of science in this country to suggest that the trained intellects capable of solving the pathological and therapeutic problems of cancer are here and only waiting for the money to tempt them to engage in these problems.—I am, Sir, yours faithfully,

J. A. Murray.

Imperial Cancer Research Fund, 8–11, Queen-square, W.C. 1, August 13th, 1923.

Medical News.

Royal Colleges of Physicians of London and Surgeons of England.—At the Final Examination of the Conjoint Board held during the month of July the following candidates were approved in the subjects indicated, but are not eligible for diplomas:—

Medicine.—B. Abelman, Liverpool; R. S. Anderson, St. Bart.'s; R. G. Anthony, Birmingham; A. J. Boase, St. Thomas's; E. G. Bradbeer, Bristol; A. Broido, Guy's; J. W. Brown, Middlesex; S. G. Brown, London; Mary Buck, Royal Free; F. B. Byrom, London; H. K. Christie, Otago; W. Clark, Charing Cross; R. F. Connell, Middlesex; R. Cove-Smith, Cambridge and King's Coll.; A. B. Cowley, St. Bart.'s; I. S. Cristol, Leeds; G. J. W. Crosby, Cambridge and Univ. Coll.; S. S. Cruden, St. Bart.'s; D. E. Cuffey, Cambridge and King's Coll.; Agnes S. Daniel, St. Mary's; A. B. Davies, Guy's; D. T. Davies, Cardiff; Margaret B. M. Dewhurst, St. Mary's; V. W. Dix, Cambridge and London; I. A. Dubinsky, Halle; H. R. Dutton, Bristol; Winifred P. Edmunds, King's Coll.; Barbara J. Edwards, Birmingham; L. C. Edwards, Cardiff and London; A. C. M. Elman, Univ. Coll.; R. B. Fawkes, Cambridge and Guy's; E. K. A. Firth, Edinburgh and St. Thomas's; H. B. Flooks, Guy's; Theodora M. Fowler, St. Mary's; H. G. Goldwater, Middlesex; H. Graf, Liverpool; F. H. K. Green, St. Bart.'s; R. D. Gross, Guy's; S. A. Gunter, St. Bart.'s; I. E. Harries and J. C. Hewetson, Guy's; G. Hochschild, St. Thomas's; Frances A. Hogben, Manchester; E. G. Holmes, Cambridge and St. Bart.'s; Dorothy M. Howse, Univ. Coll.; Gwynedd Hugh-Jones, Royal Free; L. I. Hyder, King's Coll; E. C. James, Cardiff; S. W. M. King, St. Bart.'s; P. E. M. Lanier, Middlesex; J. J. Lewenstein, Guy's; L. A. N. Line, Birmingham; R. H. Little and R. G. B. Marsh, St. Thomas's; D. G. Martin, St. Bart.'s; Lucy M. T. Masterman, St. Mary's; G. B. Matthews, Charing Cross; T. F. Meyrick and H. D. N. Miller, King's Coll.; G. O. Mitchell, Guy's; G. F. L. Mitcheson, Oxford and St. Thomas's; P. M. Moffatt, Guy's; C. I. N. Morgan and N. Moulson, St. Bart.'s; G. Murray-Shirreff, Bristol; M. Myers, Durham and Guy's; Grace H. Newell, Royal Free; F. N. Newell-Roberts, Guy's; C. E. Newman, Cambridge and King's Coll.; Doris M. Odlum, St. Mary's; F. W. Oldershaw, London; Helen E. D. E. Ornstein, King's Coll.; C. H. Owen, Liverpool; T. G. W. Parry, Guy's; P. R. Peacock, Middlesex; T. W. Preston, H. A. Robertson, and O. F. W. Robinson, King's Coll.; Sybil H. G. Robinson, London; A. B. Rufail, King's Coll.; G. Sanders, Liverpool; A. S. Simpson, King's Coll.; K. H. Southall, Univ. Coll.; T. R. Sutherland, Cambridge and St. Bart.'s; Margaret Swete and Annie Sydenham, Royal Free; W. E. C. Thomas, Cardiff; R. W. H. Tincker, St. Bart.'s; F. C. O. Valentine, Cambridge and London; Kathleen C. Vost, St. Mary's; G. M. Wadsworth, Leeds; H. F. Walker, Middlesex; and Esther Wingate and Isabelle J. Woodhouse, Royal Free.

Surgery.—R. D. Alexander, St. Thomas's; R. H. Amm, Guy's; N. F. Azer, Charing Cross; A. E. Beith, St. Bart.'s; E. M. Bergheim and M. Bersinski, Middlesex; D. R. Blunn, London; C. O. S. B. Brooke, St. Bart.'s; R. W. Brookfield, Liverpool; Lily C. Butler, Royal Free; F. B. Byrom, London; Phyllis M. S. Chalmers, Royal Free; P. S. Connan, King's Coll.; I. S. Cristol, Leeds; E. R.

Cullinan and C. H. C. Dalton, St. Bart.'s ; A. F. D. Darlington, St. Thomas's ; I. G. Davies and T. D. Deighton, St. Bart.'s ; J. E. Elam, Cambridge and St. Bart.'s ; J. A. Evans, Sheffield ; S. Farquharson, St. Thomas's ; W. H. George, London ; H. M. Golding Bristol ; T. S. Goodwin, P. D. Griffiths, and C. J. P. Grosvenor, Cambridge and St. Bart.'s ; C. C. Halliwell, Cambridge and St. Thomas's ; H. E. Harris and A. W. Hart-Perry, St. Bart.'s ; G. T. Henderson, Cambridge and Guy's ; K. W. Heritage, London ; Florence R. Hodges, St. Mary's ; J. Holmes and J. P. W. Jamie, St. Bart.'s ; J. W. W. Jepps, St. George's ; J. H. Kok, Middlesex ; R. Lang, London ; D. E. Lawrence, St. Bart.'s ; R. S. McLatchy, London ; C. I. N. Morgan, St. Bart.'s ; E. G. Morris, St. Thomas's ; O. G. Morris, Guy's ; L. N. Moss, St. Mary's ; F. W. G. Nash, Middlesex ; M. Nazmi, Univ. Coll. ; E. E. Neser, Guy's ; C. P. O'Brien, St. Bart.'s ; P. H. O'Donovan and R. J. Oliver, London ; R. Owen-Jones, Middlesex ; Amy M. Parkinson, Charing Cross ; C. V. Powell, Bristol ; R. J. V. Pulvertaft, Cambridge and St. Thomas's ; V. J. Rao, London ; R. L. Rhodes, St. Bart.'s ; W. M. Roberts, Manchester ; Nina L. D. Robertson, King's Coll. ; M. Rochfelt, Univ. Coll. ; E. J. H. Roth, St. Bart.'s ; C. J. L. Sharp, London ; H. M. Shelley, Sheffield ; F. A. H. Simmonds, St. Bart.'s ; Edith E. Stephens, Royal Free ; J. D. M. Stewart, Cambridge and St. Bart.'s ; Viva E. K. Stuart, St. Mary's ; A. K. Tateson, Otago, St. Andrew's and Edinburgh ; H. C. van Dort, Middlesex ; D. Vaughan, Guy's ; G. M. Wadsworth, Leeds ; E. R. Weaver-Adams, St. Thomas's ; H. B. White, St. Bart.'s ; R. W. White, London ; S. C. H. Worseldine, Guy's ; and H. Yates, Cambridge and St. Thomas's.

Midwifery.—A. Ahmed, Birmingham ; R. D. Alexander, St. Thomas's ; F. G. A. Armson, Birmingham ; N. F. Azer, Cairo and Charing Cross ; Georgette Bachrach and Rose Baranov, Univ. Coll. ; T. F. Barlow, London ; O. Bastable, Leeds ; E. R. Bennion, Westminster ; E. M. Bergheim, Middlesex ; E. J. Blackaby, St. Bart.'s ; L. G. Blair and D. R. Blunn, London ; W. R. Bowen, Middlesex ; E. G. Bradbeer, Bristol ; W. H. Bradfield, Guy's ; E. T. Brice, Middlesex ; W. Brockbank, Cambridge and Manchester ; R. W. Brookfield, Liverpool ; Doris D. Brown, St. Mary's ; W. G. S. Brown, Cambridge and St. Bart.'s ; E. Buchler and G. H. Buncombe, St. Bart.'s ; I. Caley, King's Coll. ; W. H. Cameron, Middlesex ; L. W. Cann and R. J. Cann, Guy's ; R. E. D. Cargill, St. Bart.'s ; J. A. Carman, London ; C. M. Carruthers, Queen's Univ. ; J. H. H. Chataway, St. Bart.'s ; Nora Cheney, King's Coll. ; H. F. Chillingworth, St. Bart.'s ; H. K. Christie, Otago ; Gladys M. Clarke, St. Mary's ; H. G. Close, Guy's ; A. M. Cooke, St. Thomas's ; Rosemary Cooke, Cambridge and Charing Cross ; C. R. Cooke-Taylor, Univ. Coll. ; A. N. Coomaraswamy, Madras and London ; A. B. Cooper, St. Bart.'s ; Margaret Corner, London ; W. H. M. Cowper, Middlesex ; D. A. L. Crawshaw, Guy's ; B. W. Cross, St. Bart.'s ; G. P. Crowden, Univ. Coll. ; D. E. Cuffey, King's Coll. ; E. R. Cullinan, St. Bart.'s ; J. Cumming, Manchester ; A. F. D. Darlington, Cambridge and St. Thomas's ; Edith M. Davies, Cardiff ; Gwladys D. Davies, King's Coll. ; J. H. T. Davies and J. R. A. Davies, Cambridge and St. Bart.'s ; P. O. Davies and T. Davies, St. Bart.'s ; Dorothy L. C. Day, London ; J. R. B. Dearden, Cambridge and St. Bart.'s ; P. H. Diemer, St. Bart.'s ; I. A. Dubinsky, Halle ; W. H. du Plessis, St. Thomas's ; Hilda R. Dutton, Bristol ; A. C. M. Elman, Univ. Coll. ; Mary H. Elmitt and Brenda H. English, Royal Free ; H. G. Estcourt, Middlesex ; D. M. B. Evans, Charing Cross ; J. P. Evans, St. Mary's ; T. J. Evans, Middlesex ; R. B. Fawkes, Cambridge and Guy's ; M. J. Finklestone, Sheffield ; Theodora M. Fowler, J. H. Francis, and H. C. Gage, St. Mary's ; J. F. Goodenough, Guy's ; T. S. Goodwin, Cambridge and St. Bart.'s ; W. Gough, Birmingham ; F. M. Graham, King's Coll. ; D. L. Greig, Middlesex ; J. L. Griffin, Bristol ; G. J. Griffiths, Middlesex ; R. D. Gross, Guy's ; J. E. S. Hamilton, Bristol ; J. G. Wan, Cambridge and St. Bart.'s ; Dorothy A. Waterfield, London ; H. J. W. J. Westlake, Guy's ; J. M. F. Whitby, St. Thomas's ; Fanny M. Whittaker, Charing Cross ; Marian E. Williams, Royal Free ; Dorothy Winstanley, Liverpool ; A. W. Wood, Birmingham ; Dorothy Wood, Charing Cross ; Isabelle J. Woodhouse, Royal Free ; H. Yates, Cambridge and St. Thomas's ; Muriel M. Yates, St. Mary's ; and Z. M. Yusuf, St. Bart.'s.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates have passed the Triple Qualification Examination :—

FINAL EXAMINATION.

Eileen M. M. Macdonald, Annie D. Allen, Morton Kahn, James L. Connacher, Claudius D. Wickramasinghe, Maurice N. Gelb, Edward T. Hale, Lawrence A. Moody, Donald G. Coutts, Howard M. Jamieson, Cyril A. Paulusz, Martha D. Devon, Duncan R. Nicol, Herman S. N. Menko, William E. Haydon, Frederick N. Spittel, Peter M'Donald Milliard, Ruby S. Beveridge, Eliazer Gelfer, and James Reid.

Medicine.—James S. Allan, Andrew Bury, Kathleen M. R. Dunn, Charles M. Hinds, James A. Kerr, Dunstair D. S. Outschoorn, William R. Robertson, Herbert E. Schokman, Arthur H. Stephenson, San Hock Tan, John G. Thomas, and Joseph R. Whitaker.

Surgery.—Elizabeth Clark, Herbert M. Hobson, James A. Kerr, Richard F. Kerr, Arthur W. H. Noble, James Ryan, and Joseph R. Whitaker.

Midwifery.—James S. Allan, Andrew Bury, Kathleen M. R. Dunn, Charles M. Hinds, Herbert M. Hobson, Percy A. M. Jayewardeni, Ronald M. Mackinnon, Patel Shankerlal Hathibhai Masters, Dunstair D. S. Outschoorn, Don Swithin M. E. Perera, William J. Rankine, William R. Robertson, Alexander Ross, James Ryan, Herbert E. Schokman, Hariprasanna Sen, Arthur H. Stephenson, San Hock Tan, and John G. Thomas.

Medical Jurisprudence.—Alexander S. Ballantine, Sudhindra Nath Bandyapadhay, Vernon Bell, John S. Caldwell, Charles Campbell, Isaac Chesarki, Mollie F. Churcher, Frederick W. Duthie, Abraham M. Filer, Alexander J. M. Findlater, Rodney H. Holb, Joseph Horsham, Constance P. H. Hunter, John A. A. Hunter, Edward N. Jamieson, William A. Kemp, Douglas J. Kynock, Jemima M. M'Kendrick, Cecil J. R. Morrison, Constance C. Reid, William M. B. Rossie, William A. Rogers, Joseph F. Sweeney, San Hock Tan, Matthew M. Tannahill, Joseph R. Whitaker, Albert E. Williamson, and Archibald C. Young.

INTERNATIONAL UNION AGAINST TUBERCULOSIS.—The Council of Directors held its annual meeting in Paris on July 26th at the headquarters of the League of Red Cross Societies, when 20 members of the Council from different countries met under the presidency of Dr. Dewez, of Brussels. Prof. Léon Bernard, secretary-general, gave an account of the development of the Union since the Brussels conference. It was decided that the following questions should be placed on the agenda of the conference to be held at Lausanne in September, 1924 :—

1. Relations between pregnancy and tuberculosis, to be reported on by Prof. Forssner (Stockholm).
2. Do there exist naturally or can there be produced artificially saprophytic forms of Koch's bacillus which might become virulent tubercle bacilli ? Report by Prof. Calmette (Paris).
3. Effects of the organisation of the anti-tuberculosis campaign in different countries on the decrease in tuberculosis mortality. Report by Sir Robert Philip (Edinburgh).

The report of Prof. Besançon (Paris) on the question of the "Respective Value of Techniques for Research on Koch's Bacillus in the Diagnosis of Lesions in Human Tuberculosis" gave rise to an interesting discussion. This report will appear in the next number of the *Bulletin*.

NATIONAL MILK CONFERENCE.—The National Clean Milk Society has convened a conference on the subject of pasteurisation, to be held on Wednesday, Nov. 21st, 1923, n the Council Chamber of the Guildhall, London, E.C. Papers will be read on: (1) Methods and Processes of Pasteurisation; (2) Physical Changes (Cream Line, &c.); 3) Chemical Changes (Salts, &c.); (4) Bacteriological Changes; 5) Biochemical Changes; and (6) Financial and Commercial Aspect. A detailed programme will be issued later.

SALFORD MILK-SUPPLY.—That some real standard of cleanliness of milk is required is made evident by Mr. J. D. Elsdon, the Salford public analyst, in his annual report on the result of previous observations and of 497 samples of milk examined for sediment during the year. What is called a very lenient standard was fixed—viz., that those amples which give a sediment of more than 5 volumes per 00,000 were characterised as adulterated. Since 1915 528 samples of milk were examined, and of these 864 were ntirely free from sediment and 1136 contained between and 1 part of sediment per 100,000 parts of milk; thus 9 per cent. of the samples examined for dirt over a period of six years contained not more than 1 part of sediment per 00,000 parts of milk. Mr. Elsdon remarks that it would ppear, therefore, that a standard of not more than 1 part of sediment per 100,000 parts of milk would be perfectly air and that milk containing 2 or more parts per 100,000 hould be classified as unsatisfactory. Moreover, "the ubject is one of peculiar difficulty, as it is quite easy for the etailer to remove the bulk of the visible dirt by filtration r decantation immediately before selling the milk. The urchaser may think, therefore, that he is getting a clean, ure article, whereas a serious bacterial contamination, which is the usual concomitant of visible dirt, entirely scapes notice. During the year standards for various milks f special grades have been issued officially, but it seems most esirable that the ordinary milk sold to the public, which, fter all, will always constitute the bulk of the milk sold in his country, should be required to come up to some standard f cleanliness both physical and bacteriological, even if this tandard is, of necessity, lower than those for the special milks mentioned." Mr. Elsdon also states that of the amples of milk—923 in number—49, or 5·3 per cent., were dulterated.

MILK (SPECIAL DESIGNATIONS) AMENDMENT ORDER SCOTLAND), 1923.—The Scottish Board of Health has issued or the information of local authorities copies of an Order which gives effect to certain amendments on the principal Order, dated June 15th, 1923. These amendments are as ollows:—

(1) *Pasteurised Milk.*—The figures of the bacterial count pplicable to samples of pasteurised milk have been increased to) before Jan. 1st, 1924, not more than 200,000 bacteria per cm.; and (2) after Jan. 1st, 1924, not more than 100,000 acteria per c.cm. The Board are advised that if pasteurised milk is handled with proper precautions, the amended figures of he bacterial count should enable distributors to sell such milk nbottled.

(2) *Grade A Milk (Pasteurised).*—The bacterial count now pplicable to Grade A Milk (Pasteurised) is (1) before Jan. 1st, 924, not more than 50,000 bacteria per c.cm. and no coliform acillus in one-hundredth of a c.cm.; and (2) after Jan. 1st, 924, not more than 30,000 bacteria per c.cm. and no coliform acillus in one-tenth of a c.cm.

Further copies of the Order may be obtained through any ookseller, or direct from H.M. Stationery Office.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—The inter session, 1923–24, will open on Oct. 2nd at 3 P.M., hen the introductory address will be delivered at the cala Theatre by Mr. Somerville Hastings, on Team Work Nature, after which the prizes gained during the previous ear will be distributed by H.R.H. Princess Alice, Countess Athlone. The annual dinner will be held the same evening 7.30 at the Trocadero Restaurant, Sir John Bland-utton in the chair. Those wishing to be present at the nner should communicate as soon as possible with the cretary-superintendent of the hospital.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD. he following awards of medical scholarships and exhibitions ave been made on the results of the Board's examination eld in June:—University College: Bucknill Scholarip: J. R. Pierre, Royal College, Mauritius. Medical xhibitions: A. S. Hatch, Bishop's Stortford College; . Levy, Central Foundation School. Westminster Hospital edical School: Natural Science Scholarship: H. J. Shorvon, ast London College. London (R.F.H.) School of Medicine r Women: Mabel Sharman Crawford Scholarship: arguerite M. Fenn, Trinity Hall, Southport. St. Dunstan's edical Exhibition: Joyce R. Woods, City of London Girls' chool. Isabel Thorne Scholarship: Decima M. Tracey, amilton House School, Tunbridge Wells. Mrs. George M. mith Scholarship: Kathleen E. Gambrell, County Secondary chool, Streatham.

WELLCOME HISTORICAL MEDICAL MUSEUM.—The museum will be closed for cleaning from Sept. 1st to 30th inclusive.

SMALL-POX IN ENGLAND AND WALES.—The number of cases reported during the week ending August 4th was only 21. Of these, 15 were from Gloucestershire, 3 from Derbyshire, 2 from the West Riding of Yorkshire, and 1 from Notts.

CODE WORDS FOR MEDICAL TELEGRAMS.—In May last the faulty transmission of a code word by telegram led to tragic delay in administering diphtheria antitoxin to a 3-year old child. The Postmaster-General has announced the disuse for such urgent telegrams of the code words for "positive" or "negative," substituting the words "present" or "not found," in regard to which no confusion would be possible.

CANCER RESEARCH IN MANCHESTER.—By means of the munificent bequest of £5000 under the will of the late Mr. Hugh Fullerton for cancer research, and a recent gift of £1000 for similar purposes by Mr. and Mrs. Todman, of Sydney, the committee of the Manchester Christie Hospital finds itself in a position to supplement the research work conducted for many years by Dr. C. Powell White. Among other suggestions, the committee has had under consideration the offer of a "Fellowship" and hopes to be in a position to announce its decision during the autumn.

DEATH OF DR. J. FERGUSON.—John Ferguson, M.B., B.S. Lond., who died suddenly in London on August 13th, was a student at St. Bartholomew's Hospital and qualified in 1904, taking his London medical degrees three years later. He was in general practice at Cheam and surgeon to the Epsom and Ewell Cottage Hospital before coming to London to take up consulting work. He was a member of the Special Neurological Board of the Pensions Ministry at Cheltenham-terrace, Chelsea, and honorary physician to the Governesses' Benevolent Institution.

INDUSTRIAL WELFARE SOCIETY.—The society will hold its fourth annual lecture conference at Balliol College, Oxford, on Sept. 14th–19th. The conference will be open to men and women welfare supervisors; employers, heads of management, labour leaders, and others are attending these conferences in increasing numbers. The provisional programme includes the following items:—Friday, 14th: 7 P.M., dinner; 8 P.M., opening address by Mr. W. L. Hichens (chairman, Cammell Laird and Co., Ltd.). Saturday, 15th: Morning, paper: Modern Factory Administration, by Mr. A. D. Denning. Afternoon, practical demonstration in industrial psychology, by Miss May Smith (Industrial Fatigue Research Board). Sunday, 16th: Morning, paper: The Romance of the Factory Acts, by Miss Constance Smith (H.M. Deputy Chief Inspector of Factories). Monday, 17th: Morning, paper: Thrift Schemes in Industry, by Sir William Schooling (vice-chairman, National Savings Committee). Afternoon, paper: Welfare Possibilities, by Mr. Eldred Hallas (National Union of General Workers). Evening, papers: The Organisation of Leisure, by three supervisors. Tuesday, 18th: Morning, special session for welfare supervisors. Afternoon, paper: Training the Young Worker, by Mr. H. Schofield (Principal, Loughborough College). The inclusive fee for membership of the conference is 75*s.*, payable in advance to the Industrial Welfare Society, 51, Palace-street, Westminster, S.W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, August 20th.—10 A.M., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards.

TUESDAY.—10.30 A.M., Dr. Paterson: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

WEDNESDAY.—10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear. 2 P.M., Mr. Gibb: Eye Dept. 3 P.M., Dr. Pernet: Skin Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Mr. Simmonds: Demonstration of Fractures. 3 P.M., Dr. Scott Pinchin: Medical Out-patients.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—10 A.M., Medical Registrar: Diseases of Children.

Daily, 10 A.M. to 6 P.M. Saturdays, 10 A.M. to 1 P.M. In-patients, Out-patients, Operations, Special Depts.

Appointments.

Dickson, C., M.D. Belf., D.P.H., has been appointed Chief Medical Officer of the Irish Free State Post Office.

Edwards, T. P., M.D., B.S. Lond., D.P.H. Camb., Medical Officer of Health to Wrexham Urban and Rural District Councils.

Galloway, D. J., M.D. Edin., to be a Member of the Executive Council of the Straits Settlements.

Neil, W. F., F.R.C.S. Eng., one of the Medical Referees under the Workmen's Compensation Act, for County Court Circuit No. 18.

Southam, A. H., M.D., M.Ch. Oxf., F.R.C.S. Eng., one of the Honorary Surgeons to the Manchester Victoria Memorial Jewish Hospital.

Vacancies.

For further information refer to the advertisement columns.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.P. and H.S. Each £100.

Birmingham, Children's Hospital.—H.P. and H.S. Each £100. Also R.M.O. £150.

Birmingham, Queen's Hospital.—Third P. for Out-patients. £50.

Blackburn County Borough.—Female Asst. M.O.H. £736.

Bristol Royal Infirmary.—Sen. Res. M.O. £300. Also H.P.'s, H.S.'s, each £120, and Dent. H.S., £156.

Burnley, Victoria Hospital.—H.S. £200.

Cape Town, Somerset Hospital.—Res. Med. Supt. £750.

Carlisle, Cumberland Infirmary.—Res. M.O. £175.

Chester Royal Infirmary.—Hon. Asst. Anæsthetist.

City of London Hospital for Diseases of Heart and Lungs, Victoria-park, E.—Half-time M.O. £200.

Colombo Municipality, Ceylon.—Third Asst. M.O.H. Rs. 9000.

Dumfries, Crichton Royal Mental Hospital.—Asst. P. £350.

East African Medical Service.—M.O. £600.

Hull Tuberculosis Sanatorium, Cottingham.—Res. Tub. O. £350.

Ipswich County Borough.—Asst. M.O.H., &c. £500.

Kent County Council.—Tuberculosis O. £696 4*s.* 8*d.*

Leamington Spa, Warneford, Leamington, &c., General Hospital.—Res. H.P. £150.

Leicester Royal Infirmary.—Locum Tenens Anæsthetist.

London Temperance Hospital, Hampstead-road, N.W.—H.P. £120.

Manchester, St. Mary's Hospitals for Women and Children.—Two H.S.'s. Each £50.

Manor House Hospital, Golders Green, N.W.—Jun. H.S. £150.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. £200.

Reading, Royal Berkshire Hospital.—Hon. Asst. P. Hon. Asst. Anæsthetist. Also H.S. £150.

Royal Naval Medical Service.—Surgeon-Lieutenants.

St. Bartholomew's Medical College, E.C.—Demonstrator of Physiology.

Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. £150.

South London Hospital for Women, South Side, Clapham Common, S.W.—First H.S. £100. Second H.S. £50. Also H.P. £100.

Staffordshire Education Committee.—Two Asst. School Med. Inspectors. £600.

Warrington Infirmary and Dispensary.—Jun. H.S. £200.

Warrington, Lancashire County Mental Hospital, Winwick.—Deputy Med. Supt. £350.

Warwickshire, King Edward VII. Memorial Sanatorium, Hertford Hill, near Warwick.—Asst. Res. M.O. £350.

West African Medical Service.—M.O. £660.

West London Hospital, Hammersmith-road, W.—H.P.; also two H.S.'s. £100.

West Riding County Council.—School Med. Inspector. £500.

York City Mental Hospital, Fulford.—Locum Tenens. £7 7*s.* weekly.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Lydney (Gloucester).

Births, Marriages, and Deaths.

BIRTHS.

Haward.—On August 11th, at The Wold, Woldingham, Surrey, the wife of Walter Haward, M.B., B.S., of a daughter.

Saunders.—On August 10th, at Lyford-road, Wandsworth Common, the wife of Dr. R. J. Saunders of a daughter.

MARRIAGES.

Boobbyer—Shaw.—On August 7th, at Christ Church, Oxford, Philip Watson Boobbyer, B.A., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P., to Vera Elisabeth Shaw, M.R.C.S., L.R.C.P., second daughter of Bishop and Mrs. Shaw, of Christ Church, Oxford.

DEATHS.

Ackland.—On August 6th, at St. James'-court, S.W., Robert Craig Ackland, C.B.E., M.R.C.S., L.R.C.P., L.D.S., aged 58.

Stenhouse.—On August 10th, at St. Andrews-place, Lewes, John Robert Stenhouse, M.D. Lond., aged 52 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE HYGIENE OF SWIMMING.

Some Feats of Endurance.

Prominence has been given to swimming as a pastime by the remarkable spell of hot weather in this country and by the fact that the English Channel has been crossed in the course of a single week by swimmers starting from either bank. The exploit of an Argentinian has easily broken all previous Channel records. The successful swims are now :—

Date of exploit.	Name of swimmer.	Age.		Distance traversed in miles.	Time.
1875 Aug. 24–25	Matthew Webb	27	Dover–Calais	45	21 h. 45 m.
1911 Sept. 5–6	Thos. Wm. Burgess	40	Dover–Calais	63	22 h. 35 m.
1923 Aug. 5–6	Henry Sullivan	34	Dover–Calais	56	26 h. 50 m.
1923 Aug. 11–12	S. Enrico Tiraboschi	35	Calais–Douvres	—	16 h. 23 m.

Captain Webb, the first champion, was 5 ft. 8 in. in height, weighed 14½ st., and had a chest measurement of 41½ in. He was freely anointed with porpoise grease before the swim but expressed a doubt whether this benefited him in any way. Much exhausted when he left the water, he yet felt as warm as when he started. He slept several times as he was being driven to his hotel, where his body temperature on arrival was found to be 98° F. On waking five hours later it was 101° F., his face was flushed, and his skin hot and dry. After further sleep he awoke apparently none the worse for his exertions except for stiffness of arms and legs and some trifling abrasions on the neck caused by the salt water. A sphygmographic pulse-tracing, however, which appeared in The Lancet of Oct. 16th, 1875 (p. 576) excited some comment on the sudden fall of the downstroke and the marked dicrotism. Mr. Burgess's achievement was the more remarkable in that he was almost 6 ft. in height and 13 years Capt. Webb's senior. He was rubbed all over with lard before entering the water. The only food which he partook during his swim consisted of Swiss milk chocolate, a few grapes, and the leg of a chicken. He was just able to walk ashore after his swim. Mr. Sullivan, who is a native of Lowell, Massachusetts, had made repeated attempts to swim the Channel from the age of 20 years. He only took nourishment once during his swim, and walked out of the water and re-embarked for Dover after two hours' rest. Sign. Tiraboschi swam fast and well throughout, drank some coffee at the critical stage of his journey, and did not seem in any distress on landing, when he was rubbed down, and within a quarter of an hour walked to the rowing boat which took him back aboard the French tug.

The Dangers of Swimming Pools.

Swimming has always taken a high place among healthy exercises. It is more and more pushed by organisers of physical training, and year by year the proportion of swimmers increases among the school-children in our inland industrial towns. It is therefore extremely important that the condition of the water in swimming baths and pools should be as pure as is reasonably possible. This point is raised by Public Health Bulletin No. 133, on the transactions of the third annual conference of State Sanitary Engineers, just issued by the Treasury Department of the U.S.A. A committee in 1921 issued questionnaires to all ear, eye, nose and throat specialists in the United States, and to a large proportion of the dermatologists asking for their experience of diseases thought to have been acquired either from the water, bathing suits, or towels used at swimming baths or pools. Seven hundred replies were received. Epidemics of mild and acute conjunctivitis were reported by 19 physicians from 12 cities in 8 States. Epidemics of furunculosis of the external ear, otitis media, and other ear infections were reported by 10 physicians from 11 cities in 9 States. Epidemics of colds, rhinitis, and sinus infections were reported by 4 physicians in 4 cities, and a similar number of epidemics of tonsillitis, pharyngitis, or laryngitis. Eight epidemics of skin infection were reported, of which two of impetigo and one of boils were attributed to infected water, while two of molluscum contagiosum, one of tinea cruris, and one of streptococcal infection were attributed to infected bathing suits and towels. One epidemic of typhoid fever was traced to a swimming pool at Louisville, Ky.; an epidemic of typhoid in a school camp was traced to bathing in a polluted stream, and another intestinal epidemic to a similar cause—a truly formidable list, even if the evidence in every case would not have convinced a court of justice. One case is mentioned where an investigation made in response to many complaints failed to find evidence of disease acquired from athing, but did find that the water was at times highly olluted. It appears from the report that regulations for he control of swimming pools and baths have been adopted n seven States. Liquid chlorine was used as a disinfectant n 27 out of 44 pools with regard to which information was upplied, but at 17 of these pools the bathers complained of he smell or taste or irritating effect of the treated water on he skin or eyes.

Hygienic Precautions.

Some aural surgeons regard public baths as a prolific ource of infected ears, witness the correspondence in our wn columns following on the announcement in 1921 of an pidemic of swimming-bath conjunctivitis and Eustachian atarrh at Freiburg i. B.[1] The tendency may be to blame he swimming bath overmuch, just as in the early days of anitation a large proportion of illness was quite unwar-antably put down to defective drains. Then most drains ere defective and now a large proportion of the population se swimming pools. Much attention is being given to nproving the water of these pools; following the example f Poplar, chlorination and continuous filtration have been uccessfully adopted at many of them. The deputy city ngineer of Hull, Mr. T. Thomas, told the recent Sanitary nstitute Congress that Hull has now three continuous ltration plants, and he referred to the Bermondsey plant hich had been working satisfactorily at the Rotherhithe aths since 1906. Swimming should be encouraged, and ttention concentrated on improving the conditions which many cases do not come effectively under the purview f the medical officer of health. This is a matter which the inistry of Health might usefully take up. School medical fficers have the opportunity of noticing any deleterious ffects of the ever-increasing use of public baths by school-hildren. Visitors to the Sanitary Congress at Scarborough his year saw the splendid open-air swimming pool con-tructed by the corporation; a similar pool is nearing ompletion at Cleethorpes. Every seaside resort worthy f the name should have an open-air swimming pool con-aining water above suspicion.

PUBLIC HEALTH IN CAIRO.[2]

THE population of the city of Cairo at the middle of 1920 as estimated at 761,300, of whom 72,770 were "foreigners," at is (presumably), non-Egyptians (including H.E. the igh Commissioner and the author of this report). It is ated, however, that this estimate (which is a reduction f 387 below the 1917 census) must be considerably below the ctual number of inhabitants, as the city has never been ore crowded than in the year under review. Also, the illage of Kafr-el-Gamûs, with a population of 1200, has been dded to the Cairo circumscription during the year; and hat is termed "Greater Helwân," embracing a considerable rea "attached to the city for all public health purposes, cept the registration of births and deaths," with an stimated population of 24,641, brings up the total of Cairo habitants to 785,941, upon which figure the zymotic iagrams are based. The birth-rate was 47·3 per 1000, as gainst 42·0 in 1919 and the same for the quinquennium; usual, there were great variations in different parts of the ty: in Bulâq the ratio was 59·5, in Esbekiya (the European arter) only 33·1. The death-rate (after deducting 1082 eaths of non-residents) was 36·3 per 1000, as compared with ·4 in 1919, 49·4 in 1918, and 40·5, the quinquennial mean. he highest district rates were registered in Bulâq (44·6), ld Cairo (44·0), and Khalifa (42·3); while in Helwân and sbekiya the ratios were only 27·0 and 27·7 respectively. he total number of infantile deaths (after deducting 178 in arious institutions, of children from outside Cairo) was 64, being in a ratio of 255 per 1000 births, as compared with 8 in 1919, and 329 in 1918. In Musky and Helwân stricts the ratios were 204 and 212 respectively; in Bulâq d Old Cairo they were 288 and 301. The main cause of eath was diarrhœa, which was very prevalent in the hot eather, the mortality being over 30 per cent. of births om the middle of May to the middle of August.

Infectious Diseases.

For infectious diseases as a whole there was a very notable provement over the experience of the two preceding years; e notifications of the eight principal diseases being only 155 per 1000, as compared with 11·659 in 1919, and 10·535 1918; the corresponding death-ratios were 1·899, 5·051, d 4·328 per 1000. For small-pox there were only 157 cases corded (0·199 per 1000), with 50 deaths (0·063 per 1000); t the fatality was high (31·8 per cent.), suggesting that any cases were not reported; indeed, 41 out of these 50 eaths were only diagnosed post mortem, as there had been medical attendance. In 1919 there had been 1455 cases ·851 per 1000) and 494 deaths (0·628). It is noteworthy that in the Musky district, where the small-pox death-rate (1·382 per 1000) had been much higher than in any other district of the city in 1919, only eight cases occurred, and not a single death, during the year under report. Possibly vaccination had been resorted to. There was a considerable increase in measles, both in cases (1·685 per 1000) and in deaths (0·514), as compared with the 1919 ratios (0·914 and 0·402); in Saiyeda Zenab the death-rate was 1·1, and in Darb-el-Ahmar 1·749 per 1000. Scarlet fever caused only four deaths in 39 cases. Diphtheria showed a considerable decrease, 0·418 cases and 0·097 deaths per 1000; 37 out of the total 329 cases, and 26 out of the total 77 deaths occurred in Darb-el-Ahmar ward (Rue de la Citadelle); while in Bab-el-Shariya and Helwân there was not a single death. Typhoid fever also was much less prevalent; the total cases numbered 925, less than in any year since 1913, the morbidity being 1·176 and the death-ratio 0·273 per 1000; the case incidence varied from 0·478 in Gamaliya ward to 1·941 in Esbekiya and 2·084 in Wayli; but the highest death-rates were registered in Khalifa ward (0·460) and Old Cairo (0·553). There has been a considerable reduction during recent years in the case-mortality, or fatality ratio, which was 43·2 per cent. in 1916, 24·9 in 1919, and 23·2 in 1920; this may probably be due to more effective notification of cases, which, of course, is most important. Typhus fever was prevalent, but less so than in the two preceding years. The cases and deaths numbered 1606 and 705, giving ratios of 2·043 and 0·897 per 1000; in 1919 the relative ratios were 6·139 and 3·344: the case mortality was also lower, 43·9 compared with 54·5 per cent. Wayli and Saiyeda Zenab had the largest numbers of cases (198 and 182), but the Musky and Abdin had the highest relative case-incidence (3·138 and 2·663 per 1000), while Darb-el-Ahmar and Old Cairo had the highest death-rates (1·545 and 1·446), the highest fatality ratios occurring in Old Cairo (66·2 per cent.) and Gamaliya (65·8). It may be supposed that the mortality ratios in these diseases are more to be relied on than those of case-incidence. Relapsing fever caused 23 deaths (0·29 per 1000), nine of which occurred in Darb-el-Ahmar; and from cerebro-spinal fever there were 15 deaths (0·019 per 1000), nine of which also occurred in the same ward. There were 1587 cases of influenza with 130 deaths (0·165 per 1000); all the deaths, except eight, occurred between the middle of January and the middle of April; there were also 1518 deaths from pneumonia and broncho-pneumonia, many of these being, no doubt, due to influenza infection. Six cases of encephalitis lethargica were notified, of which five proved fatal. At Qantara three cases of malignant pustule on the cheek occurred among the troops in August, each patient having recently bought a shaving-brush, traced to the same consignment, which had been imported from Japan in June; on examination the medical officer found one of the brushes to be swarming with anthrax bacilli; this was fully confirmed by further examination of the stock of brushes, the unsold portion of which was bought up and destroyed, though, unfortunately, they had been widely distributed in the meanwhile. Subsequent consignments were examined before being released from the Customs, several of which were found to be infected. A law was promulgated forbidding the importation of shaving-brushes, unless accompanied by a certificate from a competent authority of the country of manufacture that efficient disinfection had been carried out, and authorising the destruction of infected consignments, as well as prohibition of importation, if considered necessary.

During the year 1920, 25,169 rooms and 241,760 articles of clothing were disinfected by the Abbasiya and Fum-el-Khalig services, formalin, sublimate solution, and cyllin being used for the premises, and steam for the clothing. A "delousing campaign" was also instituted against typhus and relapsing fever, the number of contacts deloused being 1979. At the Government Fever Hospital, Abbasiya, there were 3152 admissions, as compared with 5530 in 1919; the chief diseases treated were typhus (918 admissions), relapsing fever (568), influenza (546), typhoid (172) and small-pox (109); the case-mortality ratios were 27·7, 1·2, 1·2, 32·5, and 32·1 per cent. respectively. The number of uncertified deaths which required investigation because there had been no medical attendance during the last illness was 18,814—that is, 68·1 per cent. of the total deaths that occurred in the city; this ratio is lower than in any recent year (since 1913), but still very high; in Bulâq, Old Cairo, and Khalifa districts the ratios were 83·4, 84·4, and 85·6 per cent.; in Esbekiya only 23·3 per cent.

Preventive Measures.

The condition as regards infant vaccination does not appear to be quite satisfactory; there were 30,215 primary vaccinations of native children, which works out at 85·8 per cent. of the births, a fairly high and satisfactory ratio; but of the 656 children of foreign birth only 408 were vaccinated—that is, 62·2 per cent.; the nationality of these children is not stated. An important part of the public health organisation is that of the Passenger and Pilgrim Control Service; as many as 7951 persons arrived in Cairo from countries under supervision on account of being infected, a considerable increase on the arrivals (4288) in the previous year. The largest numbers (2958 and 2301) came from Syria and Turkey; 58 per cent. landed at Alexandria and 32 per cent. at Port Said, the remainder at Suez. In addition 19,646 Egyptian Labour Corps men from the Canal Zone required to be observed on entering Cairo. The supervision of "unhealthy, inconvenient, and dangerous establishments" (such as bakeries, groceries, dyeworks, stables, &c.) is another important, and difficult, duty; the conditions were found to be faulty in only 6·60 per cent. of the 14,667 inspection visits, an increase, however, on the ratio (5·5) in 1919; bakeries (26·8 per cent.) and confectionery establishments (22·0 per cent.) were the worst; but among the grocers (4613) and butchers (3558), which between them compose more than half the total, faulty conditions were found in only 4·0 and 1·1 per cent. respectively; even in dairies and milkshops not more than 14·6 per cent. were found to be unsatisfactory. At all police stations and outposts suitable arrangements have now been made for the reception and examination of injured persons, and police officers have been instructed in the elements of first-aid; a specially arranged medical chest has also been supplied for each fire-brigade motor. All men joining the police force are now vaccinated, and an anti-lice campaign has been instituted as a protection against typhus and relapsing fever. The amount of medical work carried out by the police medical officers appears to have been very considerable; as many as 8036 examinations of persons were made for injury or supposed injury (compared with 6029 in the previous year); 2088 cab-drivers and carters were examined for the Traffic Office, and 3219 *ghafirs* on account of sickness. Anti-mosquito work was carried out in certain selected areas where the inhabitants allowed access to their premises for dealing with possible breeding places; the Gezira area has benefited materially by the drainage work carried out in 1919–20. At Helwân *Culex* is found in the town almost exclusively and *Anopheles* in the outskirts.

---

[1] THE LANCET, 1921, ii., 519 et seq.

[2] Government Press, Cairo. 1921.

At the conclusion of this most interesting report, Dr. P. G. S. Williams, medical officer of health for the city, mentions a measure likely to prove of great value to the public health that is being carried out in the smaller streets of the native quarters; this consists in laying down a paving of cubical stone setts, placed upon a clean sand foundation, and giving an impermeable surface, which can be kept clean. An improvement in the health of the inhabitants may be hoped for in the quarters so dealt with, and especially in the incidence of infantile diarrhœa. The report is well illustrated with diagrams and tables, and extremely well printed; the addition of a plan of the city, showing its present divisions, might be suggested.

THE EFFECT OF BACTERIAL EXTRACTS ON BLOOD-SUGAR.

IT is well known that substances such as peptone and certain proteins contained in yeast will lower blood-sugar when injected subcutaneously. Hopes were raised early in the year that "yeast insulin" might prove an effective remedy and that quantities of it would be available for clinical trial in the near future. In the current issue of *Nature* Messrs. L. B. Winter and W. Smith report briefly on their further work at the Biochemical Laboratory in Cambridge. They have now obtained from the action of micro-organisms, other than yeast, extracts which lower the level of blood-sugar in normal animals to a point where convulsions occur. These convulsions were relieved by injection of glucose, so that it is presumed they were not due to toxic substances in the injections. Such extracts seem to lower the level of blood-sugar for a longer time than does insulin itself, and it remains to be seen whether they can be utilised in the treatment of diabetes. Experiments to this end are being continued and will be followed with interest.

TO PARENTS OF DEFECTIVE CHILDREN.

A LITTLE book entitled "Opening Doors" (London and Edinburgh: Oliver and Boyd. 1923. Pp. 20. Cloth 1*s*. 6*d*., paper 6*d*.) has been written by Dr. John Thomson for the mothers of mentally defective infants "in the hope that it may provide them with some of the instruction and encouragement of which they are often much in need." In the early months of a baby's life it is the mother who almost invariably has the best and sometimes the only opportunity of discovering whether her baby's development differs from that of a normal infant; and where this is the case there are many ways in which she can help him, many doors which she can at least place ajar for him, if any abnormality present be recognised sufficiently early. At present, as Dr. Thomson points out, a large proportion of mentally defective children begin to be educated for the first time when they are between 5 and 7, having had practically no training during the earlier and more receptive years of life; and the circulation of information of the kind contained in this book cannot but make the subsequent training of such children easier. The advice given is simple but eminently practical, and is so worded as not to offend the most susceptible of mothers. She is shown what she can do for her baby if he is forming bad habits; if he is doing or noticing too little; if he is late in speaking, cries constantly, or has fits; and how she can strengthen his character and keep him strong and well. Suggestions are given for the special treatment of children whose limbs are stiff, these including active and passive movements, as well as a number of miscellaneous common-sense hints. The value of this small book is out of all proportion to its size, and it should meet with a warm welcome not only from mothers, but also from child welfare workers, nurses, and even doctors.

A TUBERCULOSIS DIRECTORY.

A FOURTH edition has just appeared of the useful Handbook of Tuberculosis Schemes, issued by the National Association for the Prevention of Tuberculosis (20, Hanover-square, London, W. 1. 10*s*. 6*d*., post free). Its aim is to give ready and trustworthy information regarding the operation of tuberculosis schemes and other tuberculosis activities throughout Great Britain and Ireland, to produce, in fact, a tuberculosis directory as far as mortality and provision for control and treatment are concerned. Any complete tuberculosis scheme, as the foreword indicates, includes the operations of a care-committee, and it is satisfactory to note that in a number of instances local authorities have frankly coöperated with voluntary agencies and have included in their schemes institutions established and maintained on voluntary lines. The Handbook now contains a number of tables and graphs effectively showing the varying death-rates in counties and boroughs for the year 1922. It will be found helpful by all who are interested in the development and administration of sound anti-tuberculosis measures.

THE SAN FRANCISCO MEDICAL MEETING.

THE recent annual meeting of the American Medical Association at San Francisco was attended by over 3750 medical men, this number exceeding that of 1915—when the Association last met in that city—by nearly 1500. The extensive publicity given by the press to the proceedings of the session is believed by Californian physicians to have been of great service in combating the advertising of non-medical cults which are particularly powerful in that State. The sessions of the House of Delegates, the governing body of the Association, were fully and closely attended, and many problems of professional and public importance were discussed. An innovation was introduced in the shape of clinics held in connexion with the meeting, both before and after it, throughout the Pacific Coast and Western States, in order to bring home the scientific work of the Association to those who were unable to be present at the actual gathering in San Francisco. At the first meeting of the House of Delegates on June 25th the Speaker, Dr. Frederick C. Warnshuis, of Grand Rapids, Mich., claimed that certain members and parts of the Association had during the past year used the promulgation of public health measures as an excuse to justify "the institution of socialised medicine for all classes of society," and that on that account "condemnation and ridicule are directed to the profession as a whole." If unity of purpose was to be nullified by the acts and attitude of certain special groups of members, the Association might as well withdraw from the public arena and concern itself only with purely scientific topics. Others of Dr. Warnshuis's recommendations referred to increased representation of the Association in the group of medical authorities who have been discussing, and are again expected to discuss, the organisation of a national welfare department in Washington, and to the cessation of any necessity for the Red Cross organisation to enter into public health or community clinic work. Dr. George E. de Schweinitz, of Philadelphia, President of the Association, spoke in his address of the ever-present question of the time which should be devoted to specialties in the undergraduate curriculum, and suggested that from the central offices of the Association a questionnaire of wide scope should be sent to graduates of representative schools of medicine in various parts of the country prior to the next meeting on medical education, and that an analysis of the replies received should be presented as a basis of discussion. Dr. Ray Lyman Wilbur, of California, President-elect, emphasised the necessity in medical affairs of decentralisation of organisation, in order that the special needs of each State might be met by those who best knew its problems. Dr. Wilbur also referred to the increasing interest throughout the country in the practice of periodical physical examination; the doctor trained to thinking in terms of disease must, he said, turn his attention to thinking in terms of being well.

"The underlying principle of the book is sound and commendable, and the author has succeeded admirably in his aim."—BRITISH MEDICAL JOURNAL.

London: J. & A. CHURCHILL, 7, Great Marlborough Street, W. 1.

STUDENTS' GUIDE—SESSION 1923-1924.

THE scheme upon which the Students' Number of THE LANCET is constructed will make it easy, we hope, or all who consult it to find what they seek. The General Council of Medical Education and Registration s the controlling authority of all the medical and dental education of the country, and its responsibility for he upkeep of the Medical Register and for the maintenance of the examination standard is first explained.

But the student has to be taught as well as examined, and as the systems under which instruction can be btained do not conform to one pattern, the various curricula are described in detail, and under their espective headings the necessary information will be found concerning the facilities for medical study offered t the different teaching centres of the United Kingdom. The regulations for the examinations, both reliminary and professional, at these centres are set out so that the student desiring to obtain a medical legree from any university, or a diploma from any medical corporation, may ascertain the course of clinical nstruction and the conditions under which submission for examination has to take place. The metropolitan nedical schools and hospitals are grouped under the University of London, of which they are constituent odies, although their educational opportunities are offered to students of other universities as well as to those eeking the qualifications of the medical corporations. A similar plan is adopted in dealing with the provincial niversities, the hospitals in direct connexion with which are described with the universities; the hospitals nay not be official schools of the universities. but they supply an integral section of the teaching required.

Upon securing degrees or diplomas admission to the Register follows, and greater education begins. he prudent young doctor already knows what he or she desires to make the next step, and there is a arge range of choice displayed. The inducements to enter one of the Services should prevail more than hey have done of recent years. An account is given of the conditions under which commissions can be btained in the Navy, Army, Indian, and Air Force Medical Services, and in the Colonial Medical Service.

ENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

OWERS, DUTIES, AND CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE powers and duties of the General Medical ouncil, or "General Council of Medical Education nd Registration of the United Kingdom" to give the ouncil its full title, have been set out in detail in nany previous Students' Numbers of THE LANCET. t is first a registering body: no person, even though is qualifications have been obtained by examination, a legally qualified medical practitioner until his ame appears on the Medical Register. Secondly, it is standardising body, ensuring that medical education reaches an efficient standard by scientific xamination. Thirdly, it is a penal and disciplinary ody, having power to remove from the Register any ractitioner adjudged guilty of conduct "infamous a a professional respect." Fourthly, to the Council committed the codification of pharmaceutical emedies. The duties of the Council are thus primarily f a public nature, and its construction shows its tness for its fourfold responsibilities.

The Council at present consists of 38 members, f whom, as will be seen by the annexed list, all but 1 are official representatives of some corporate body. ive members are chosen by the Crown on the advice f the Privy Council, and six others are elected by he members of the medical profession as Direct epresentatives. There are also three additional embers appointed by the Privy Council under the entists Act, 1921, under which the powers and uties of the General Medical Council with regard to e keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to e Dental Board of the United Kingdom (see p. 432).

President of the General Council: Sir Donald acAlister. Members of the General Council: Sir umphry Rolleston, chosen by the Royal College of hysicians of London; Mr. H. J. Waring, F.R.C.S., oyal College of Surgeons of England; Dr. Benjamin loomfield Connolly, Apothecaries' Society of London; r. Arthur Thomson, F.R.C.S., University of Oxford; r. Wynfrid Laurence Henry Duckworth, University Cambridge; Dr. Robert Howden, University of urham; Sir Sydney Russell-Wells, University of ondon; Dr. Robert B. Wild, Victoria University of anchester; Sir Gilbert Barling, University of irmingham; Dr. Richard Caton, University of iverpool; Dr. Thomas Wardrop Griffith, University Leeds; Mr. John Beresford Leathes, M.B., University of Sheffield; Sir Isambard Owen, University of ristol; and Dr. David Hepburn, University of Wales. Dr. William Russell, chosen by the Royal College of Physicians of Edinburgh; Sir James Hodsdon, Royal College of Surgeons of Edinburgh; Dr. James Alexander Adams, Royal Faculty of Physicians and Surgeons of Glasgow; Dr. H. Harvey Littlejohn, University of Edinburgh; Sir Donald MacAlister, University of Glasgow; Dr. Matthew Hay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore, chosen by the Royal College of Physicians of Ireland; Sir Arthur Gerald Chance, Royal College of Surgeons in Ireland; Dr. Edward Magennis, Apothecaries' Hall of Ireland; Dr. Andrew Francis Dixon, University of Dublin; Dr. Denis Joseph Coffey, National University of Ireland; and Mr. Thomas Sinclair, F.R.C.S., Queen's University of Belfast. Nominated by His Majesty, with the advice of his Privy Council: Sir Francis Henry Champneys, Sir George Newman, Sir Nestor Tirard, Sir Leslie Mackenzie, and Sir Edward Coey Bigger. Elected as Direct Representatives: Dr. J. A. MacDonald, Sir Thomas Jenner Verrall, Dr. Robert A. Bolam, Mr. E. B. Turner, Sir Norman Walker, and Dr. Leonard Kidd. Treasurers of the General Council: Mr. H. J. Waring and Sir George Newman. The three additional members are Mr. William Henry Dolamore, M.R.C.S., L.D.S.; Mr. William Henry Gilmour, M.D.S., L.D.S., and Mr. William Guy, F.R.C.S.E., L.D.S.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

The following are the General Medical Council's Regulations in regard to the registration of medical students which came into force on Jan. 1st, 1923.

Registration of Medical Students.

1. Subject to such exceptions as the Council may from time to time allow, every medical student, at the commencement of his studies, should be registered in the manner and under the conditions hereinafter set forth.

2. Before registration as a student every candidate should produce evidence that he has attained the age of 17 years.

3. The minimum standard of General Education required is that of University matriculation or entrance examination in the Faculties of Arts or Pure Science.

4. Before registration as a student every applicant should be required to have passed an approved examination n general education, and, in addition thereto, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies.

University of Oxford: Radcliffe Infirmary and County Hospital.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. The hospital contains 210 beds. In connexion with the hospital there is usually held in each year during October a post-graduate course, lasting a week.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being a graduate of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing two Special Examinations for the ordinary B.A. degree, or an Honours degree in one of the Triposes. The Natural Sciences Tripos is taken most frequently, as some of the subjects are practically the same as those for the first and second M.B.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for M.B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) General and Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *second* is divided into three parts—viz., (1) Organic Chemistry, (2) Human Anatomy and Physiology; and (3) Pharmacology and General Pathology. The *third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic.

Candidates who have passed both parts of the third M.B. examination are admitted to the registrable degree of *Bachelor of Surgery* (*B.Ch.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A., to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery* (*M.Ch.*) the candidate must have passed all the examinations for B.Ch., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Ch.

New regulations for Medical and Surgical Degrees are being drafted, to come into force in October next.

Diplomas are granted in Public Health, in Tropical Medicine, in Medical Radiology and Electrology, and in Psychological Medicine. Candidates must hold a recognised medical qualification.

Women Students.—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the First and Second M.B. Examinations under certain conditions.

University Prize in Medicine.—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, The Registry, Cambridge.

Diploma in Medical Radiology and Electrology.—This Diploma is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The Diploma is only open to those who hold a medical qualification, and includes a course of lectures and practical work in physics (Part I.), and in Radiology and Electrology (Part II.). Attendances at the necessary course of lectures in both subjects and in addition six months' clinical experience in an adequately equipped hospital recognised by the Committee is essential. The whole course of study takes six months, the lectures, practical work, and hospital attendance running concurrently. The Courses carried out by the University of Cambridge are at present arranged to begin early in January. Three months are spent in Cambridge doing the lectures and practical work in Part I., attending the systematic lectures in Part II., and the practice of Addenbrooke's Hospital, where there is a fully equipped and up-to-date X ray and Electrological Department. The remaining three months can be completed at any recognised hospital, but special arrangements are made for students to continue their studies in London, where demonstrations at various hospitals are arranged in order to give a wide experience. In addition, an independent course is arranged by the British Association of Radiology and Physio-Therapy. This Course is held entirely in London, but is recognised by the University as qualifying for the examination, and begins early in October. Further particulars as to the Cambridge Course can be obtained from Dr. F. Shillington Scales, Medical Schools, Cambridge, and of the London Courses from Dr. Stanley Melville, at the Offices of the B.A.R.P., 12, Stratford Place, London, W. 1.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament, 1898, and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Lecturers were also appointed in special subjects.

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby; or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*).

The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W. 7.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) *Attended* prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry, including Bio-Chemistry: Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools.

The First Examination for Medical Degrees (*Inorganic Chemistry, Physics, including Mechanics, and General Biology*) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (*Part I.*): *Organic Chemistry, including Bio-Chemistry.*—This examination will take place twice in each year, commencing on the Tuesday following the third Monday in March and on the second Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (*Part II.*) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in-Hospital; (14) The conduct of at least 20 Labours; (15) Ante-natal Clinic; (16) Experience as a

Clinical Clerk in Gynæcological Work; (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology and Rhinology. A thesis may be submitted as for M.D.

Fees.—Matriculation £2 12*s.* 6*d.* for each entry. at provincial examinations an additional local fee is charged. First examination for Medical Degrees: £6 6*s.* for each entry to the entire examination. For re-examination in one subject the fee is £2 2*s.* Second examination, Part I. £3 3*s.*, repeated on each subsequent entry; Part II. £9 9*s.* for the whole examination. Third examination: £12 12*s.* for each entry to the whole examination. M.D. Examination: £21; for re-examination £10 10*s.* M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Principal Officer. University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. It receives over 9000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day, except Saturdays, at 1.30 P.M., and Surgical consultations are held on Thursdays at the same hour. Medical consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical lectures on all special subjects are also given. Wholetime Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board, and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

New Buildings.—The new buildings comprise residential quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the Medical College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, pathological histology, and pathological chemistry. *The Medical School Buildings* include three large lecture theatres, a large dissecting room, a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. *Laboratory Instruction for the D.P.H.* is provided during the winter and summer sessions. Facilities for research work are afforded in the Clinical Units and the Laboratories of the pathological and other departments. The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Scholarships given in aid of Medical Study.—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships of the respective values of £75 and £100; (*c*) Entrance Scholarship in Arts, £100; (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, and Anatomy; (*c*) and (*d*) are awarded after examination in Latin, Mathematics, and Greek or French or German; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The more important of the other Scholarships and prizes are as follows:—Four Junior Scholarships—(*f*) No. 1, £30, Anatomy and Physiology; (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3, £25, Chemistry, Physics, and Biology; (*i*) No. 4, £15, Chemistry, Physics, and Biology; (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (*n*) Sir G. Burrows Prize, 10 guineas, Pathology; (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; *p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105; *r*) Lawrence Research Scholarship and Gold Medal n Pathology, awarded by election, £115; and *s*) Baly Scholarship in Clinical Medicine, £105, awarded by examination.

---

[1] For Ancillary Metropolitan Medical Schools see p. 393.

Information may be obtained on application to the Dean to the Medical College: Dr. T. W. Shore. The Warden of the Residential College is Mr. R. M. Vick.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Examination and Treatment.

Appointments.—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year after competitive examination.

Primary and Intermediate Studies.—By an agreement with the University of London the School sends ts Primary and Intermediate Students to receive heir lectures and practical work at King's College, which is situated within four minutes' walk.

Final Studies.—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica, Toxicology, and Operative Surgery.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School. Students receive heir training in Preventive Medicine, Pathology, and Bacteriology here, and are encouraged to undertake Research. Special facilities are available for Post-raduate Research and Study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital adjoining. Special ectures and demonstrations are arranged for Post-raduates.

The *Museum* contains over 4000 specimens, ncluding a notable collection of over 800 gynæco-ogical specimens, "The Cuthbert Lockyer Collection."

Students' Club.—The social comfort and con-enience of students are met by library, reading, and smoking-rooms, refreshment-room, &c. The Club, which is under the control of a Committee of Students, rovides needful athletic recreation, and includes the Medical Society. An athletic ground, comprising six cres, has recently been acquired and is now in use.

Women Students.—Women students are admitted o the School and Hospital upon the same terms and onditions as men, and after qualification are eligible or resident Hospital appointments.

Fees.—Now under revision.

Further information may be obtained on application o the Dean, Dr. W. J. Fenton, Medical School, haring Cross Hospital, London, W.C.

ST. GEORGE'S HOSPITAL.—This hospital has a service f 436 beds, of which 180 are allotted to surgical, 150 o medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for iseases Peculiar to Women, and a Maternity Ward f 11 beds has been instituted recently. Children's eds are placed in the women's wards. Two wards re allotted to ophthalmic cases.

Entrance Scholarships and Endowed Prizes of a otal value of £600 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at that College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Eight house physicians and eight house surgeons are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the post (2) of Senior Anæsthetists at £50; the posts (2) of Junior Anæsthetists, each at £30. The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, lawn tennis, boxing, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Scholarships and Prizes.—At this school two entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two University Entrance Scholarships, 90 guineas and £70 respectively, Anatomy and Physiology. This year, in addition to these Scholarships, Exhibitions, each of the value of £40 and up to eight in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*c*) William Brown Exhibition, tenable for two years and open to perpetual pupils having registrable qualifications, £135 per annum, Practice of Medicine, Midwifery, and Surgery; (*d*) William Brown Exhibition, tenable for three years and open to perpetual pupils qualified not more than three years previously, £49 per annum, Essay and Original Work; (*e*) Allingham Scholarship in Surgery for Students qualified not more than three years, £60, Competitive Essay; (*f*) and (*g*) two Brackenbury Prizes, one in Medicine and one in Surgery, £30 each, open to students of not more than five years' standing; (*h*) H. C. Johnson Memorial Prize, £19, Practical Anatomy; (*i*) Pollock Prize, £23, Physiology, Physiological Chemistry, and Histology; (*j*) Clarke Prize, £5; (*k*) Thompson Medal, £5, Clinical Reports; (*l*) Brodie Prize, £7, Clinical Reports; (*m*) Webb Prize, open to perpetual pupils, £30, Bacteriology; (*n*) Sir Francis Laking Memorial Prize £65, open to students having registrable qualifications.

Further information may be obtained from the Dean of the Medical School, Dr. J. A. Torrens.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 626 beds. The whole of the medical school has been rebuilt during the last 27 years. It provides ample accommodation, with modern equipment, for all the non-clinical subjects of the medical curriculum. Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anæsthetists, surgeons' dressers, medical clinical clerks, post-mortem clerks, extern obstetric dressers, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit. There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

The following new Clinics have been opened: Salomon's Welfare Centre (for Maternity and Children), Tuberculosis Department, and V.D. Department.

Scholarships. — Six entrance scholarships are awarded annually as follows :—(*a*) one War Memorial scholarship, providing a free Medical Education for five years of the value of £200, to be awarded alternately in Arts and Science (next award, July, 1924, Science); (*b*) one Arts scholarship of £100 for students under 21 years of age, Latin, English, Greek, or French or German, Arithmetic, Euclid, and Algebra; (*c*) one Science scholarship for students under 21 years, £100; subjects, any two of the following: Inorganic Chemistry, Physics, and Biology; (*d*) a Junior Science scholarship of the value of £100 is offered for competition, annually in July, to candidates who have attended Preliminary Science Classes at this School; (*e*) two open Science scholarships: (1) a War Memorial scholarship of the value of £80, awarded annually in September; (2) an open scholarship of the value of £80, awarded annually in September, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School; subjects, any two of the following: Anatomy, Physiology, Organic Chemistry, Pharmacology, General Pathology.

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates, the term " military service " meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the war; or (2) in respect of other approved duties in connexion with national defence.

The Dean of the Medical School is Professor T. B. Johnston, from whom further information may be obtained.

UNIVERSITY OF LONDON: KING'S COLLEGE.—The medical department (Faculty of Medical Science) at this College only deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants to students entering the College directly and also to students of the following four hospital schools which prepare only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital. The department is open to both men and women.

Scholarships.—(*a*) Two Warneford Entrance Scholarships of £30 each for four years. Examination in July, subjects selected from Divinity, Classics, Science. (*b*) Sambrooke Scholarship of £25 for two years. Examination in May, subjects selected from Mathematics, Physics, Chemistry, Botany, Zoology, and Geology. (*c*) Worsley Scholarships: £100 in five annual instalments of £20. (*d*) Rabbeth Scholarship of £20 for best work in first year. (*e*) Second Year Scholarship of £20 tenable for one year. (*f*) Daniell Scholarship of £40 for one year. Awarded on results of University Honours Examination.

Fees.—Tuition fee of 35 guineas for the first year, £42 for the second and third years, with a materials fee of 4 guineas in the first year, 6 guineas in the second year, 4 guineas in the third year. For prospectus and further information application should be made to the Dean of the Medical Faculty (Professor E. Barclay-Smith).

Dental Course.—The College, in association with King's College Hospital, have instituted a Dental Diploma Course.

Fees.—First year (Chemistry and Physics), 20 guineas; second and third years (Anatomy, Physiology, Dental Mechanics, and Dental Metallurgy), 52 guineas per annum. Fourth and fifth years (Hospital), 60 guineas per annum. For prospectus and further information application should be made to the Secretary, King's College Hospital Medical School, Denmark Hill, S.E.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The advanced subjects in the curriculum are taught at the Medical School attached to King's College Hospital, which is situated at Denmark Hill, S.E. 5. The hospital stands in the midst of a South London population, from which an immense amount of clinical material is forthcoming. During the past year there were 198,456 attendances in the out-patient and casualty departments. There are 400 beds available for in-patients, and provision will ultimately be made for 600 beds. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physicotherapy, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry. The appointments open to students are those of clinical assistant to the special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers: resident anæsthetist; bacteriologist; clinical pathologist; pathological registrar; and medical, surgical, and obstetric registrarships. Fourteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Prizes.—(*a*) Warneford Scholarships, (*b*) Sambrooke Scholarship, (*c*) Rabbeth Scholarship, £20 (see above); (*d*) Medical Entrance Scholarships, £50 (Anatomy and Physiology), and £50 (Pathology and Pharmacology) open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (*e*) A Medical Entrance Scholarship in Science, value £50, tenable for five years, successful candidates to study at King's College and King's College Hospital; (*f*) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (*g*) Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital; (*h*) Carter Prize, £15, Botany; (*i*) Tanner Prize, £10, Obstetrics and Diseases of Women; (*j*) Todd Prize, £4 4*s*. and medal, Clinical Medicine; (*k*) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the nomination of the Regius Professors; (*l*) an Epsom College Scholarship, value £50, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London. The Warneford and Sambrooke Scholars are required to take the subjects of the preliminary and Intermediate examinations at King's College, and the final subjects at King's College Hospital.

Athletics.—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. Admirable playing fields, over six acres in extent, have been provided for the use of the students on Dog Kennel Hill, Lordship-lane, S.E., about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of " The Platanes "—a hall of residence available for students belonging to the hospital.

Fees.—The composition fee for Hospital work and Final subjects of the curriculum is 93 guineas if paid in one sum, or 95 guineas if paid in two instalments, in addition to the Entrance Fee of 10 guineas. The Calendar of the School will be sent on application to either of the following: Dr. H. Willoughby Lyle, *Dean*; Mr. S. C. Ranner, *Secretary of the Medical School*, King's College Hospital, Denmark Hill, S.E. 5.

LONDON HOSPITAL.—The hospital, with its Medical College and Dental School, is situated in the Mile End-road, E. The hospital contains 950 beds, which are in constant use, and is the only general hospital for East London. During last year 17,444 in-patients and 107,455 out-patients received treatment, while 215 major operations were performed. 32,427 out-patients attended the special departments for diseases of the Eye, Ear, Nose and Throat, Skin, Teeth, &c., and the Orthopædic, Venereal, Radiological, Electro- and Physico-Therapeutical and Inoculation Departments. The hospital presents, therefore, a large field for clinical instruction, and in its Wards and Out-patient Departments exceptional opportunities are afforded for acquiring an extensive and practical experience in all phases of disease.

The Clinical Units in Medicine and Surgery coördinate the teaching of their subjects in the Hospital. The directors and their assistants give practical instruction in Elementary Clinical Medicine and Surgery to all students before they are allowed to enter the Wards and Out-Patient Department. Senior Students are encouraged to work with the units. Special courses of lectures and demonstrations are arranged in Medicine and Surgery and their ancillary subjects. Opportunities for research will be provided under the supervision of the staffs of the units.

Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital. Holders of resident appointments have free board. Special classes are held for the examinations of the University of London, or the Fellowship of the Royal College of Surgeons, or the Membership of the Royal College of Physicians, and for other higher examinations. A course of post-graduate training is held in the work of School Clinics for School Medical Officers (actual and ntending) and others. Special entries for medical nd surgical practice can be made. A residential Hostel on hospital grounds is provided for the convenience of students. The Clubs Union Athletic Ground of over 13 acres is within easy reach of the hospital.

Scholarships and Prizes.—At this school the uccessful candidates for the first items in the list here hown must enter for the course subsequent to passing the examination in Biology, Chemistry, and Physics. The value and the subjects of examination are as follows:—Price Scholarship £100, and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarhip, open to students of Oxford and Cambridge Universities, £52 10*s*., Human Anatomy and Physiology; Buxton Prize, £31 10*s*., subjects f Anatomy and Physiology; three Prizes for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynæcology; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine, and Surgery; Letheby Prizes (2), 25, Chemistry and Chemical Pathology; eight Dressers' Prizes, amounting to £40, zeal, efficiency, nd knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £40, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 espectively; Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology; James Anderson Prizes (4), £20, Elementary Clinical Medicine; Arnold Thompson Prize, £15, Medical and Surgical Diseases of Children; and Liddle Prize, triennial, 120.

Medical Research Funds.—Research Funds of over 26,000, including the Eliza Ann Alston Endowment Fund for Medical Research, provide valuable scholarships for men wishing to undertake research or desirous of preparing Theses for University degrees.

Dean: Professor William Wright, London Hospital Medical College, E.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The Hospital and Medical School are situated close to Paddington station (G.W.R.) having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 305 beds and, by a scheme of affiliation, for teaching purposes, of the Paddington Infirmary, Paddington Green Children's Hospital, and Maida Vale Hospital for Nervous Diseases, the teaching facilities extend over 1000 beds. The Athletic ground (10 acres) is situated at Wembley and can be reached in 30 minutes by a constant service of trains. A large pavilion has recently been added.

Clinical Facilities.—Clinical Units in Medicine and Surgery were established in 1920, and have now been formally recognised by the University Grants Committee. St. Mary's being one of the six Medical Schools in London which enjoy this privilege. Lying-in beds have recently been added, and, in addition to this, arrangements have been made by which all students take out a short course of instruction in Practical Midwifery at Queen Charlotte's Hospital without additional fee.

Institute of Pathology and Research.—Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S.

Appointments.—Three Research Scholarships of £200 each are awarded annually to students working in the departments of the institute; and preparation is being made to open 13 research beds. Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually.

Complete Curriculum.—The Medical School provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Entrance Scholarships.—Three Entrance Scholarships of the value of £210 each are awarded annually.

Fees.—Composition Fee for entire curriculum (5½ years) £200 in one sum, or £210 by four annual instalments. Composition Fee for Clinical curriculum (2½ years) 90 guineas in one sum, or 95 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas.

MIDDLESEX HOSPITAL.—The hospital contains over 450 beds, with special wards for Cancer, Maternity and Gynæcological and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin; Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electro-Therapeutic department. The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electro-Therapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

The Medical School, which now includes the Bland-Sutton Institute of Pathology and the Cancer Research Laboratories is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly, commencing in April and October. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 Professors, 29 recognised Teachers, 8 Demonstrators, 4 tutors. The Bland-Sutton Institute of Pathology is completely equipped for routine hospital investigations, teaching and research work, and contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility for study.

Other features of interest are: the institution of a course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone. Primary F.R.C.S. class will resume in August.

Special classes are held to prepare students for the Intermediate Examinations of the Universities.

Hospital Appointments.—All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anæsthetist, and two resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. The medical, surgical, and obstetric and gynæcological registrars are appointed as vacancies arise. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department. Eight Registrars are appointed annually.

Scholarships, Prizes, &c.—(*a*), (*b*), and (*c*). Three Entrance Scholarships, value £100, £50, and £25, and (*d*) a University Scholarship, value £50, are awarded annually in September. The successful candidates are required to become general students of the school. (*e*) A Freer Lucas Scholarship for Foundationers or Council Exhibitioners of Epsom College is awarded annually on the nomination of the Headmaster. There are also, (*f*) and (*g*), two Broderip Scholarships, value £60 and £40 respectively; (*h*) the Lyell Gold Medal and Scholarship, value £55 5*s.*; (*i*) the John Murray Medal and Scholarship, value £25 (awarded every third year); (*k*) the Freeman Scholarship, value £30; (*l*) the Hetley Clinical Prize, value £25; (*m*) the Leopold Hudson Prize, value 11 guineas; and (*n*) the Second Year's Exhibition, value 10 guineas. There are also numerous class prize examinations.

Fees.—The fees are arranged on a basis of an annual payment of approximately £42 for the five years of the curriculum. After five years, if the student is not qualified, the annual fee is £21.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, Musical Society, the cricket club, the football clubs, the athletic club, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. There are a restaurant and gymnasium in the school buildings, and large athletic grounds at Wembley, with new pavilion. A subscription to the Amalgamated Students' Club is payable by all General and Dental students. Full particulars on application to the Dean, Middlesex Hospital Medical School, W. 1.

St. Thomas's Hospital.—This Hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 632 beds. The in-patients last year numbered 8639, whilst the number of attendances as out-patients, including the casualty and light departments, was 466,951. There are special departments for the treatment of women, children, the eye, ear, nose and throat, skin, teeth, and for orthopædics. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for light treatment, X rays, and the Physico-therapeutics are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day, except Saturdays, at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. All appointments in the hospital are open to students without extra fee. Appointments open to students before qualification: Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists. The Students' Club comprises a spacious restaurant and smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments Open to Students after Qualification.—A Resident Assistant Physician, a Resident Assistant Surgeon, and a Resident Anæsthetist are appointed annually at a salary of £200 each per annum. Two Hospital Registrars, Medical and Surgical, at an annual salary of £250 each are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An Obstetric Tutor and Registrar, an Ophthalmic Registrar (at an annual salary of £50 each), and an Orthopædic Registrar (unpaid) are appointed yearly. Ten Resident Casualty Officers and Anæsthetists (including two Senior) are appointed every six months. Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months. Eight Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for re-election. There are three Assistants in the Department of Pathology; the Senior receives £600 a year, and the two Juniors £450 each.

Fees.—The annual fees are: For each year of study £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first year of study; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in any two of the following subjects: Anatomy, Physiology, and Chemistry. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Cheselden Medal, Surgery and Anatomy; (*e*) Mead Medal, Medicine, Pathology, and Hygiene; (*f*) Toller Prize, Medicine, Pathology, and Hygiene; (*g*) Bristowe Medal, Pathology, and Morbid Anatomy; (*h*) Solly Medal and Prize, biennially, Surgical Reports; (*i*) Cutton Memorial Medal in Clinical Surgery, iennial ; (*j*) Wainwright Prize, Medicine, Pathology, nd Hygiene ; (*k*) Hadden Prize, Pathology ; (*l*) Beaney Scholarship, £50 biennially, Surgery and Surgical Pathology ; (*m*) Sutton Sams Prize, bienially, reports of cases in Obstetric Medicine ; (*n*) Grainger Testimonial Prize, £31 10*s.* Anatomy and Physiology ; (*o*) Louis Jenner Research Scholarship, enable for two years, £60 annually, Pathology ; and p) Research Scholarship, tenable for two years, £200 er annum.

The Dean of the Medical School is Sir Cuthbert S. Vallace, and the Medical Secretary Dr. A. Elliot, rom whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—Jniversity College has been constituted a University entre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments f Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences) ; also the Departments f Anatomy, Physiology and Pharmacology (the Internediate Medical Sciences), and the Department of Hygiene and Public Health. Research work is underaken in all departments. The completion of the nstitute of Medical Sciences, which the generosity f the Rockefeller Foundation made possible, provides xceptional facilities for research and post-graduate tudy in anatomy, physiology and pharmacology. In articular might be specified the opportunities for nvestigation in human and comparative embryology nd neurology, in histology, radiology, anthropology, iochemistry, and experimental physiology and xperimental embryology. Arrangements have also een made for the closer correlation of work in the nstitute with that of University College Hospital and s Medical School.

Faculty of Medical Sciences.—Composition Fees.—For the courses required by the University of London. . For the First Medical Course, 35 guineas, entitling o one attendance and to the privileges of the Union ociety for one session. 2. For the Second Medical Intermediate) Course 80 guineas, payable in two nstalments of 40 guineas each. This fee entitles to ttendance at Anatomy and Physiology during three ears and to one attendance at Organic and Applied hemistry, Pharmacology, and Materia Medica, and o the privileges of the Union Society or the Women's nion Society for two sessions.

For the medical education required by the Examining oard in England and the Society of Apothecaries. irst examination, Parts I., II., III., 29 guineas, ntitling to attendance for the First and Second Terms nd to the privileges of the Union Society for one ession ; 35 guineas, entitling to attendance throughout ne session and to the privileges of the Union Society r one session. First Examination, Part IV., and econd examination, 80 guineas, payable in two instalents of 40 guineas each. This fee entitles to attenance during three years in all subjects but Practical harmacy and to the privileges of the Union Society r two sessions.

Scholarships and Prizes.—The first three items on ne present list require a complete intermediate course University College. The money value and subjects examinations are as follows : (*a*) The Bucknill cholarship, 135 guineas ; (*b*) and (*c*) two Entrance xhibitions, 55 guineas each, Chemistry, Physics, otany, and Zoology ; (*d*) Cluff Memorial Prize, £15 ennially, Anatomy, Physiology, and Chemistry ;) Schafer Prize in Physiology, £18 triennially ;) Sharpey Physiological Scholarship, £105, Biological ciences ; (*g*) Morris Bursary for sons of deceased rofessional men, by nomination, tenable for two ears, £16 a year ; and (*h*) five Gold and five Silver edals awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL. -Dean : Sir George Blacker. Vice-Dean : Mr. Gwynne Villiams. Secretary : Mr. G. E. Adams. Open to en and a limited number of women students. Fees for Preliminary and Intermediate Course : See under University College. For the Final M.B., B.S. (London) Course, 112 guineas if paid in one sum, 115 guineas if paid in two instalments, as follows—first year, 70 guineas ; second year, 45 guineas. This fee entitles to attendance on lectures and hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, Durham, and other British Universities, and for the medical education required by the Examining Board in England and the Society of Apothecaries. There are over 300 beds in the hospital.

Clinical Units in Medicine and Surgery are now in operation. The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Outpatient Department of the hospital. A Unit in Obstetric Medicine will be established as soon as the new Obstetric Hospital now in course of construction is finished.

The new buildings of the Obstetric Hospital of 60 beds (rendered possible by the Rockefeller Benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension to the Nurses' Home, and the new research laboratories for the Medical School, are well under way, and these buildings should be ready for occupation by the spring of 1924.

Special Departments, Clinical and Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments tenable by Students.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Twelve house physicians, eight house surgeons, four senior and four junior obstetric assistants (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital : Resident Medical Officer, Surgical Registrar, Obstetric Registrar, Harker-Smith Cancer Registrar, Casualty Medical Officer and a Casualty Surgical Officer, Assistants in Ear and Throat, Ophthalmic, Skin and Venereal Diseases Departments, and House Anæsthetist.

Museum of Pathological Anatomy.—The Museum is open for study from 9 A.M. to 5 P.M. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston.

The Anatomical Museum of the University of London, University College, is open to all students of

University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 13,500 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the Medical School are required to become members. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London University College, is situated near the G.W.R. station at Perivale.

Scholarships and Prizes.—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions, 112 guineas each, Anatomy and Physiology; (*e*) Graham Scholarship in Pathology, £300 per annum for two years, awarded by the Senate of the University of London; (*f*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*g*) Atchison Scholarship, tenable for two years, £55 per annum, General Proficiency in Medical Studies; (*h*) Magrath Clinical Scholarship, about £100, Clinical Cases; (*i*) Percival Alleyn Scholarship, about £60, Surgery; (*j*) Filliter Exhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10*s*., Practical Surgery; (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*m*) two Liston Gold Medals for Clinical Surgery; (*n*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*o*) Tuke Silver and Bronze Medals for Pathology. (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology. (*q*) Leslie Pearce Gould Travelling Scholarship for Surgery.

Residence of Students.—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers.

Westminster Hospital.—The hospital contains 225 beds and affords relief to upwards of 1600 in-patients and 25,000 out-patients annually. There are separate departments for Diseases of the Eye, Skin, Teeth, Ear, Nose, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, for Venereal Diseases, and for Massage, Electrical and Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments are open to male and female students.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £70 each. Summer Session: Two Scholarships in Anatomy and Physiology, £70 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Notes of Cases; Clinical Surgery Prize, £5, Notes of Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, tenable for two years, £20, Chemistry; Rabbeth Scholarship, open to First-year Students, £20; Class Examinations in the Preliminary Scientific Course; and the Sambrooke King's College Scholarship in Science, value £25. Inquiries and requests for Prospectus may be addressed to the Dean, Dr. A. S. Woodwark.

London (Royal Free Hospital) School of Medicine for Women, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £240 in five instalments. This sum includes library and laboratory fees. Arrangements are made for pre-medical courses in Chemistry and Physics, which are included in these fees.

The Royal Free Hospital contains 240 beds. The Hospital also has large Casualty and Out-patient Departments, and Departments for Special Diseases. A new and specially equipped block contains the Obstetrical and Gynæcological Unit which, with the Marlborough Maternity Department, controls 68 beds. A Maternity District is attached to the Unit. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, South London Hospital, and Royal London Ophthalmic Hospital.

An agreement has been made under which a certain number of students of the school may attend full clinical courses at St. Mary's Hospital, Paddington (305 beds).

Courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the Royal London Dental Hospital, Leicester-square.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants, clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, 5, Mecklenburgh-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies.

Scholarships and Prizes.—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years and next to be awarded in 1925. (*d*) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1927, £90. (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1926, £14 10*s.* (*i*) John Byron Bursary, tenable from two to four years, for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st; next award in March, 1924, £20. (*k*) Helen Prideaux Prize, awarded every second year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £40. (*l*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (*m*) Sarah Holborn Scholarship, vale £20 a year for three or five years, awarded every alternate year; next award in 1925. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s.* a year, awarded in alternate years; next award in July, 1925. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1924. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2*s.* and £1 1*s.* are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5*s.*, is awarded yearly. The Edith Pechey Phipson Prize in Pharmacology, value £3 3*s.*, is awarded annually. There is also a small loan fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help. Prizes and Certificates of Honour are awarded in each class at the end of the session.

The Dean of the Medical School is Miss Aldrich-Blake, M.D., M.S.; the Honorary Secretary, Dr. May Thorne; and the Warden and Secretary, Miss L. M. Brooks, to whom inquiries may be addressed.

UNIVERSITY OF DURHAM.

Two Diplomas, one Licence, and seven degrees are conferred—viz., the Diploma in Public Health, Diploma in Psychiatry, the Licence in Dental Surgery, and the degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, and Doctor of Hygiene.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Anatomy, Elementary Biology, Chemistry, and Physics. The subjects of the Second Examination are—Anatomy and Physiology. The subjects for the Third Examination are—Materia Medica and Pharmacy, Pharmacology, Medical Jurisprudence, Public Health, and Pathology and Elementary Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Therapeutics, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children. It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special examination in the Theory and Practice of Medicine. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Doctor of Surgery.—The University of Durham grants the Degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, and not less than 24 years of age. They must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery and ancillary subjects. One at least of the three years must be spent in the University. The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology and Bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad. The fee for the examination is £20, and the fee for the degree is £10.

Candidates for any of the above degrees, diplomas, or licence, must give at least 28 days' notice to Professor Howden, Registrar, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before the 1st of April.

Scholarships and Prizes.—In connexion with this University the following Scholarships and prizes are awarded:—(*a*), (*b*), (*c*), and (*d*). Four Scholarships of £25 a year each, tenable for four years; the examination will be the September Matriculation Examination. Candidates must take English, Latin, Arithmetic, Euclid, Algebra, Geography, English History, and one, or two, of the three languages—French, Greek, German. (See College Calendar for special books.) Open to candidates desirous of being admitted as Medical Students. The successful candidates must take out their entire curriculum at the University of Durham College of Medicine, Newcastle-upon-Tyne. (*e*) Pears Scholarship of £50 a year (when vacant), tenable for three years; Matriculation Examination.—At the College of Medicine are: (*f*) Dickinson Scholarship, interest on £400 and gold medal; examination in Medicine, Surgery, Midwifery, and Pathology. Open to full students of the College of Medicine who have passed the third M.B. Examination. (*g*) Tulloch Scholarship, interest on £400; examination in Elementary Anatomy, Biology, Chemistry, and Physics. (*h*) Charlton Memorial Scholarship, interest on £700; examination in Medicine. Open to full students of the College entered for the class on the Principles and Practice of Medicine. (*i*) Gibb Scholarship, interest on £500; awarded annually as a Scholarship in Pathology to full student who passes the best examination in that subject. No student is eligible after completion of his curriculum. (*j*) Luke Armstrong Memorial Scholarship, interest on £680: Original Essay in Comparative Pathology. Open to all Graduates in Medicine or Hygiene and candidates for these degrees who have spent six months at the University and whose age does not exceed 30 years. (*k*) Stephen Scott Scholarship, interest on £1000; Original Essay on any Surgical subject. Open to any graduate in Medicine or Surgery of the University or any student of the College of Medicine. Student's age must not exceed 30 years. (*l*) Heath Scholarship in Surgery, of the value of £200, awarded every second year. All Graduates in Medicine or Surgery of the University are eligible. (*m*) Philipson Scholarships (2). The interest on £1800 to the candidates who obtain the highest marks in the Final M.B., B.S. Examinations held in March and June respectively. (*n*) Gibson Prize, interest on £250 stock; examination in subject of Midwifery and Diseases of Women and Children. Open to students who have attended one course of lectures on Midwifery and Gynæcology. (*o*) Outterson-Wood Prize, interest on £250, in Psychological Medicine. (*p*) Turnbull Prize and Medal; examination in Surface Anatomy. Open to students at end of their second winter session.—At the Royal Infirmary is (*q*) Goyder Memorial Scholarship, interest on £325, awarded annually to student who most distinguishes himself in Clinical Medicine and Clinical Surgery at the Royal Infirmary. For further information apply to Professor R. Howden, Registrar of the College.

The College of Medicine, Newcastle-upon-Tyne.—Clinical instruction is given at the Royal Victoria Infirmary, containing about 550 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Post-graduate classes are held.

The Bacteriological Laboratory.—A new Bacteriological Laboratory has recently been erected adjacent to Armstrong College.

Newcastle-upon-Tyne Royal Victoria Infirmary.—The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII. in 1906. The number of beds is 550. The number of in-patients annually is 11,500 and out-patients' attendances 276,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians and Assistant Surgeons, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1923 opens on Oct. 2nd and the summer session of 1924 on April 15th. Applications for detailed information should be made to the Dean, Dr. Horsley Drummond, at the hospital.

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is further taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye.

Post-Graduate Courses.—General and Special Post-Graduate courses are held under the joint auspices of the Council and the College of Medicine, the honorary staff of the Royal Victoria Infirmary, and the British Medical Association.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof, and a recognised Pre-Medical Examination in Chemistry and Physics. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Part I., Elementary Biology and Organic Chemistry.—Part II., Anatomy and Physiology. Second Examination.—General Pathology and Bacteriology, Materia Medica, and Practical Pharmacy. Third Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, Therapeutics, and Special Pathology. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital one month, and mental hospital three months. Vaccination instruction must be taken out and courses of Ophthalmology, Venereal Diseases, Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver, for the M.Ch. A thesis of exceptional merit may exempt from any part of these examinations.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and to submit themselves for oral and possibly written examination.

Fees.—Matriculation, £2; First Examination, Part I., £2 10*s.*; First Examination, Part II., £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £2 10*s.*; Final Examination, £10; M.D. or Ch.M., £12 10s.

At the University of Birmingham the following Scholarships are awarded:—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. Birm. candidates, tenable at some University or Hospital in Great Britain or Ireland, or abroad, (*b*) two Ingleby Scholarships of £10 each, awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*e*) Dental Scholarship of £37 10*s.*, Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10*s.* each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate passing the Final M.B., Ch.B. in June, who obtains the highest marks in Clinical Medicine, provided the marks so gained be not less than 60 per cent. The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in the fourth and fifth years (open to all students).

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board. The hospitals possess more than 600 beds, treating annually about 9000 in-patients and 70,000 out-patients. The curriculum is adapted in the first place to the University of Birmingham, but it also meets the requirements of the examinations of other licensing bodies. At the General Hospital there are open to the students the following appointments: A surgical registrar, £200 per annum; a resident medical officer, elected annually (£155); a resident surgical officer, elected annually and eligible for re-election for three years (£180); a resident pathologist, elected for six months (£100); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £70 a year; two house surgeons to the gynæcological, ophthalmic, and aural departments are elected every six months, receiving board, residence, and a salary of £70 a year; two assistant house surgeons are elected every three months, receiving board, residence, and salaries at the rate of £40 a year, and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £70 a year. One casualty house surgeon who holds office for three months at salary at rate of £70 a year. Four non-resident obstetric students who hold office for one month and receive board only on payment of one guinea per week. Thirty-eight other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Mental Hospitals, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopædic and Spinal Hospital, at the Maternity Hospital, and at the Ear and Throat Hospital.

Post-graduate Courses.—A Lectureship in Morbid Psychology was established in 1919 in the University, and courses of lectures are given annually by specialists in the subject. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers. Post-graduate Courses of Clinical Demonstrations (for General Practitioners) at the Birmingham General and Queen's Hospitals were held from April to June, 1923. Further courses will be arranged later.

BIRMINGHAM GENERAL HOSPITAL.—371 beds are in daily use, 6000 in-patients per annum. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, Septic and Infectious cases; special beds for Eye and Skin cases. About 50,000 out-patients per annum. Laboratories for Bacteriology and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments which include those for Radium, Electro-therapy, Extern Midwifery, and Venereal Diseases. Post-graduate classes are held in every branch of medicine and surgery. The Jaffray Branch Hospital contains 56 beds.

QUEEN'S HOSPITAL (Beds 224).—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynæcology and ophthalmology, dentistry, radiography, pathology, bacteriology, massage, electricity, whirlpool baths, electro-cardiograph, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of 250. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available on various subjects when a sufficient number of graduates are present. A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Doctor in Philosophy (Ph.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 21 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry, Inorganic, Organic, and Physical; (2) Biology (Zoology and Botany); and (3) Physics. The examination is divided into two parts—namely, (1) Chemistry and Physics, and (2) Biology; and candidates may present themselves in these parts separately. The subjects of the Second Examination are (*a*) Anatomy and Physiology (including Physiological Chemistry and Histology), and (*b*) Materia Medica and Pharmacy and Pharmacology. Candidates may present themselves in (*a*) or (*b*) separately. The subjects for the Final Examination are: (1) General Pathology, Morbid Anatomy, and Bacteriology; (2) Forensic Medicine, Toxicology, and Public Health; (3) Obstetrics and Diseases of Women; (4) Surgery, Systematic, Clinical, Operative, and Practical, including Ophthalmology; (5) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children, and Therapeutics. The Final Examination is divided into three parts, the first consisting of subject (1), the second of subject (2), the third of subjects (3), (4), and (5). Candidates may present themselves in these parts separately. Candidates for the third part must have completed the fifth year of medical study.

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least two years have elapsed since he passed the examinations for those degrees, or, in the case of the degree of Doctor, unless, having obtained substantially equivalent degrees in an approved University, he has subsequently spent two years in the University or in the Clinical School in the performance of research or the conduct of systematic clinical observations. Candidates for the degree of Doctor of Medicine are required to present either a published thesis together with, if desired, other published work, or an unpublished thesis together with copies of original work published in scientific journals or in the proceedings of scientific societies or otherwise. An examination is required if the work submitted is not of special merit. If the work submitted is of special merit but extremely specialised a candidate may be asked to submit a reasoned report on a subject set by the examiners.

The University has recently established a Diploma in Medical Radiology and Electrology—Part I., Physics; Part II., Radiology and Electrology. The parts may be taken at one examination or separately.

At this University the following Scholarships and Fellowships and Prizes are awarded:—(*a*) and (*b*) Robert Gee Entrance Scholarships, two annually, of £25 each, tenable for two years, Joint Matriculation Board Examination held in July, open to First M.B. Course Students; (*c*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects, Perpetual Course at the University; (*d*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination among Senior Students in Anatomy, Physiology, Pharmacology, and Materia Medica; (*e*) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects, and Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students; (*f*) University Scholarship of £25 for one year, awarded on results of Second Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £100 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Bio-Chemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £150, for one year; (*m*) Ethel Boyce Fellowship in Gynæcological Pathology, of £100, for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; Samuels Memorial Scholarships, three at £20; numerous prizes and medals.

Medical School Buildings.—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. A new building for Tropical Medicine has recently been opened.

Clinical Instruction.—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of six special hospitals—the Eye and Ear Infirmary, the Hospital for Women, Liverpool Maternity Hospital and Ladies' Charity, the Royal Liverpool Children's Hospital, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1140 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine is awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the first M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations. (These are now under revision.)

The First Examination.—(1) Chemistry and Physics; (2) Biology. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Inorganic and Elementary Organic Chemistry and Physics; Part 2, Biology. The candidates may pass in these parts separately under certain conditions.

The Second Examination. — (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. Candidates may pass in (1) and (2) separately under certain conditions.

The Third Examination.—(1) Pathology; (2) Pharmacology and Therapeutics. These subjects may be taken separately under certain conditions.

The Final Examination.—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts.

Candidates for the Second Part of the Final Examination must have completed the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Scholarships, Fellowships, and Prizes.—At this University there are 22 Foundation Scholarships, 12 Exhibitions, five being for subjects connected with medical study, a Surgical Prize, a University Fellowship (Leech Fellowship, £100), Research Fellowships in Public Health, and Honorary Research Fellowships. 13 Entrance Scholarships are tenable for Medical courses; one Scholarship is offered in Surgery, Biology, Physiology, and Diseases of Children respectively, and one General Medical and Surgical. Exhibitions are offered in Physiology and Anatomy, and one for French and German. "The Dumville" Surgical Prize is awarded on the results of the Final Examination in Surgery in the Summer Term, £15. The Leech Fellowship (£100) is for the encouragement of study and research, and is open to persons who have graduated M.B., Ch.B., in the University not more than 18 months previously. The Honorary Research Fellowships, tenable for two years, conferring the right of free use of the laboratories, are awarded generally in October on application, with evidence of capacity for independent investigation.

There are many entrance scholarships, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and a library. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Clinical Instruction.—THE MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 671 patients. The medical side consists of five units, each unit having a testing room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing, and apparatus rooms, and its own class-room attached. All of these units are occupied. The fine educational block provides very handsomely for the wants and comforts of the students, there being separate suites of rooms for the men and the women, and also a large common reading room, a lecture theatre, and a museum. The present annual average number of in-patients is 13,650, of out-patients 27,000, and the list of casualties in the accident room has averaged 17,000 per annum. About 9000 operations are performed annually in the operation theatres. Associated with the infirmary are: (1) the Convalescent Hospital at Cheadle, containing 136 beds; (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the city for casualty and out-patient work, and 50 beds for pensioners. The Associated Hospitals thus contain 1244 beds and are under the same management. Women students are admitted on the same terms as men.

Fees.—Medical Practice: Three months, 7½ guineas; six months, 12 guineas; 12 months, 18 guineas; full period required by the Examining Boards, 60 guineas.

Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College Syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

The Dean of Clinical Instruction is Dr. T. H. Oliver.

Manchester Children's Hospital, Pendlebury, Gartside-street, Manchester, and St. Anne's-on-the-Sea.—The hospital contains 190 beds and 28 in the Convalescent Home, St. Anne's-on-the-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electro-therapeutic Department. Two Clinical Assistants are appointed for periods of three or six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is a new Orthopædic Department. A special out-patients' day is held on Friday mornings at Gartside-street, and a ward at Pendlebury is devoted to cases needing operative treatment. Out-patients are seen daily at 9 A.M. at the Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 70 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Zoology and Botany. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Disease and Diseases of Children; Surgery—Systematic, Clinical, and Practical; Obstetrics, and Gynæcology—Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

These conditions are at present under review in connexion with the recommendations of the General Medical Council.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, may be required to pass an examination.

The first term commences on Oct. 1st. Prospectus, &c., can be obtained from the Dean of the Medical School.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods may do so on terms which may be obtained from the Dean.

Clinical Instruction.—**The Leeds General Infirmary**, in connexion with this medical faculty, has accommodation for 632 in-patients, including 88 beds at branch hospitals in the country. During the last year 10,277 in-patients and 41,857 new out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Asylum and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

The First Examination.—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

The Second Examination.—The subjects of the examination are Anatomy and Physiology.

The Third Examination.—The subjects of the examination are Pathology, Pharmacology, Anatomy and Physiology. Candidates must have completed the Lent Term of the fourth year of professional study.

The Final Examination.—The subjects of the examination are Medicine (including Forensic Medicine, Public Health, Mental Diseases, and Diseases of Children); Surgery; and Obstetrics (including Gynæcology). Candidates must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the egree of Doctor of Medicine must have passed the amination for the degrees of M.B., Ch.B. at least ne year previously, must present a thesis embodying bservations in some subject approved by the professor medicine, and must pass an examination in the rinciples and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have ken the M.B, Ch.B. at least one year previously, nd must since have held for not less than six months surgical appointment in a public hospital.

The subjects of examination are Systematic, inical, and Operative Surgery, Surgical Anatomy rgical Pathology, and Bacteriology.

Scholarships, &c.—At this University, in addition four Edgar Allen scholarships of £125 a year for ree years, holders of which can take the courses the Faculty of Medicine, there are 8 scholarships nd a Town Trust Fellowship. Full particulars as to rriculum, scholarships, &c., may be had on applica- on to the Registrar or to the Dean of the Medical aculty.

The Medical School.—The new buildings of the niversity opened in 1905 are situated at the west nd of the city, adjoining Weston Park, and the edical Department occupies the entire north wing the University quadrangle. The various athletic nd other students' societies are under the manage- ent of the Union Representative Council, elected nnually. There are large and comfortable common oms both for men and women students. A refectory open daily at the University where students may btain refreshments, lunch, dinner, &c., at extremely oderate prices. The University journal, *Floreamus*, lited by a committee of staff and students, is ublished each term. The University Halls, "Oak- olme," Clarkehouse-road, and "Tapton Cliffe," lwood-road, are recognised by the Senate as lls of residence for women students; full par- culars may be obtained of the tutor for women udents.

Clinical Instruction.—The University is within easy ach of the various hospitals with which it is connected r clinical purposes. These are as follows: The OYAL INFIRMARY (Secretary, Mr. J. W. Barnes), ntaining 326 beds, with an annual average number over 3800 in-patients, over 11,500 out-patients, and er 23,000 casualties; the Royal Hospital (Hon. Sec., o *tem.*, to the medical and surgical staff, Mr. Vincent ownrow), with 191 beds, and an annual number of 00 in-patients, over 20,000 out-patients, and nearly ,000 casualties; and the Jessop Hospital for iseases of Women, with 80 beds, about 900 -patients, and about 3057 out-patients; also a aternity department, with about 450 in-patients r annum and about 700 out-patient cases attended. ecial courses on Fevers are held at the City Fever ospitals (600 beds) and on Mental Diseases at e South Yorkshire Asylum (1610 beds). For rposes of clinical practice the practices of the yal Infirmary and Royal Hospital are amal- mated, giving a total of 511 beds for the treatment medical, surgical, and special cases. There are ecial departments for the treatment of Diseases the Eye at each institution, with wards assigned to em. In addition to these the Royal Infirmary has ecial departments for the treatment of Diseases of e Skin and Ear, with beds assigned to them, whilst the Royal Hospital there are special out-patient partments for Diseases of the Throat, Ear, Skin, thopædics, and Mental Diseases. Instruction is o given at the South Yorkshire Asylum (1694 ds). During the last year over 6000 patients ssed through the wards of the two institutions, ile those attending as out-patients numbered er 45,000. The department of Pathology and cteriology in the University is fitted with every quirement for the most advanced work in these bjects.

Fees.—The Medical Composition Fee is £38 a year each of the five years.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics, of which three shall have been passed in the University, and two of these three subsequent to pass in the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). Parts I. and II. may be passed separately or together.

The Final Examination.—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). Candidates may pass I. and II. together, or separately, and Forensic Medicine and Toxicology may, at the option of the candidate, be taken either with Part I. or Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery. The degree may be taken also in General Surgery, and a Special Subject—e.g., Oto-Rhino-Laryngology, Ophthalmology, and Gynæcology.

Clinical Instruction.—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye Throat, and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well-equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Appointments.—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological and ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate: At the Bristol Royal Infirmary: Four house surgeons, £120 each per annum; two house physicians, £120; resident obstetric and ophthalmic house surgeon, £120; throat, nose, and ear house surgeon, £120; dental house surgeon, £120. All these appointments are made for twelve months. From the resident officers a senior resident officer is appointed at a salary of £200. At the Bristol General Hospital: Senior resident medical officer, £300 per annum; casualty house surgeon, £125 per annum; two house physicians, £125 per annum; house surgeon, £125 per annum; special obstetric physician, £125 per annum; house surgeon to special departments, £125 per annum; dental house surgeon, £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship, value £45, open to women only; Two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value 7 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10*s.*, for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose, and throat, value £14.

Daily Post-graduate Study.—For those who are able to devote several hours each day to hospital practice the University offers special facilities for Post-graduate work. Qualified medical practitioners may be appointed as Clinical Assistants for a period of one or more months. They may act as Assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Fee, £3 3*s.* per month.

Post-graduate Clinical Work. — Demonstration courses with weekly lectures are held during May, June, and July. Fee, £2 2*s.* All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

This University has, inter alia, the privilege of granting Degrees in Medicine, and Diplomas in Public Health and Tuberculous Diseases. Preliminary courses of study for the Degrees in Medicine may be pursued at any of the constituent Colleges of the University—viz., at Aberystwyth, Bangor, Cardiff, or Swansea. The Welsh National School of Medicine is situated in Cardiff and is an integral part of the University College there.

University College, Cardiff. Welsh National School of Medicine.—This School is staffed on the Unit System and whole-time Professors of Medicine, Surgery, Pathology, Preventive Medicine, Physiology, and Anatomy have already been appointed. Professors of Obstetrics and Gynæcology, and Tuberculosis, and a Lecturer in Materia Medica and Pharmacology have also been appointed. There are also Lecturers appointed in the various special subjects. The Courses of Instruction, which are open to both men and women students, are adapted to meet the needs of those preparing for Degrees in Medicine and Surgery in the University of Wales, and certain of them also for Degrees in other Universities, and for the Diplomas of licensing bodies.

Students can complete the whole of their curriculum in the School, and qualify for the degrees of M.B., B.Ch. in the University of Wales. Hospital instruction is given at the Cardiff Royal Infirmary, at the City Lodge Hospital, and at other recognised Institutions. The attention of students about to matriculate is drawn to the numerous entrance scholarships offered for competition at the University College, Cardiff, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. Medical men wishing to prepare for the Diploma in Public Health or the Tuberculous Diseases Diploma of the University of Wales can attend complete courses of instruction in the School. Prospectuses can be obtained on application to the Dean of the Faculty of Medicine, or to Mr. D. J. A. Brown, Secretary, at University College, Cardiff.

Clinical' Instruction.—King Edward VII. Hospital, Cardiff: Founded 1837. 450 beds.—Swansea General and Eye Hospital: Hospital, 260 beds, 225 civilians, 35 (sailor and soldier pensioners); Convalescent Home, 26 beds.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

1. *Regulations applying to all candidates who passed he required Preliminary Examination in General Education before Jan. 1st*, 1923.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral and partly practical. These examinations will be held in the months of January, April, July, and September or October unless otherwise appointed. Every candidate must give notice in writing to Mr. F. G. Hallett, O.B.E., Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, W.C., 14 clear days before the day of the examination, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, and Elementary Biology. A candidate may take this examination in two parts at different times (Chemistry and Physics must be taken ogether until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same ime at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, and in Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a ecognised institution. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of ejection, and he will be re-examined in the subject or ubjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce vidence of further instruction at a recognised instiution. Any candidate who shall produce satisfactory vidence of having passed an examination for a degree n Medicine in any of the subjects of this examination onducted at a university in the United Kingdom, in ndia, or in a British colony will be exempt from xamination in those subjects.

The fees for admission to the *First Examination* re as follows: For the whole examination, First dmission, £10 10*s.*; re-examination in Chemistry, 3 3*s.*; re-examination in Physics, £2 2*s.*; re-examinaon in Biology, £3 3*s.* Second Conjoint: This xamination is in two parts—viz.: Part I., Anatomy nd Physiology; Part II., Materia Medica and harmacology. A candidate must have attended at recognised medical school, lectures on Anatomy, hysiology, and a course of Practical Physiology nd Histology, and have dissected for twelve onths during the ordinary sessions. He must also tend three months' lectures or demonstrations in harmacology and receive instruction in Practical harmacy. Part II. may be passed at the same time s Part I., or before or after that part, provided the onditions of admission to the whole examination ave been fulfilled. The study of Anatomy and hysiology before passing in two of the three subjects the first examination is not recognised. If rejected, candidate before being admitted to re-examination ust continue his studies at a recognised medical hool for not less than three months.

Second Examination: £10 10*s.*; re-examination in art I., £6 6*s.*; re-examination in Part II., £3 3*s.*

The subjects of the *Third* or *Final Examination* e: Part I., Medicine, including Medical Anatomy, thology, Therapeutics, Forensic Medicine, and ublic Health. Part II., Surgery, including Pathogy, Surgical Anatomy, and the use of Surgical ppliances. Part III., Midwifery and Diseases eculiar to Women. Candidates may present themlves for Parts I., II., and III. of the examination parately or together at the expiration of not less an two years (24 months) from the date of passing e Second Examination on production of the certifites of study required for the respective parts, ovided that the examination is not completed fore the expiration of five years from the date of ssing the Preliminary Examination.

The fees for admission to the *Third* or *Final Examination* are as follows: Third Examination: £21; re-examination in Part I., Medicine, £6 6*s.*; Part II., Surgery, £6 6*s.*; Part III., Midwifery and Diseases of Women, £4 4*s.* Members of English, Scotch, or Irish Universities £5 5*s.* for first admission to the examination and £36 15*s.* for the diplomas.

A candidate referred on the *Third* or *Final Examination* will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

2. *Regulations applicable to candidates who passed the required Preliminary Examination in General Education on or after Jan. 1st*, 1923.

Students are required to pass a *Pre-Medical Examination* in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognised by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any University recognised by the Board; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, and the Joint Matriculation Board of the Northern Universities. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed. The examination is partly written, partly oral and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months and he must produce evidence of further instruction in the subject or subjects of failure. The fee for the examination is £3 3*s.*, for re-examination in Chemistry £2 2*s.*, and for re-examination in Physics £1 1*s.*

There are two Professional examinations called the *First* and *Final Examinations*. The courses of study for these examinations must not be commenced until the Pre-Medical examination in Chemistry and Physics or some equivalent examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology. (*b*) Physiology, including Bio-Chemistry. Section II. Pharmacology, Practical Pharmacy and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Bio-Chemistry and Bio-Physics during five terms, courses of instruction in Pharmacology, Practical Pharmacy and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s.*, for re-examination after rejection in Section I. £6 6*s.*, for re-examination after rejection in either part of Section I. £3 3*s.*, for re-examination after rejection in Section II. £3 3*s.* A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. (*a*) Pathology, including Morbid Anatomy, Morbid Histology and Clinical Pathology. (*b*) Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from Section I. The fee for admission to Section I. is £4 4*s.*; for admission to Section II., Part I., £10 10*s.*; Part II., £10 10*s.*; Part III., £6 6*s.*; and the re-examination fees are respectively £3 3*s.*, £6 6*s.*, £6 6*s.*, and £4 4*s.*

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, and in Tropical Medicine and Hygiene. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, a Colonial, or a Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W.C.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—Every candidate must have attained the age of 25 years, and be already registered or have passed a qualifying examination in accordance with the Medical Act of 1886, or obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British colony, or foreign qualification, for which the courses of study and the examinations have been adjudged by the Censors' Board to be satisfactory. The nature and extent of this examination will, in the case of each candidate, be determined by the Censors' Board. All other candidates must produce proof of having passed the examinations required for the Licence of the College. The examination is directed partly to pathology and partly to the practice of medicine. The fee for admission as a Member of the College is 40 guineas, except when the candidate for Membership is a Licentiate of the College, in which case the fee already paid for the Licence shall be deducted from the 40 guineas. The fee for the examination is £6 6*s.*

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:

THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce and include the examination of patients and the performance of operations on the dead body. The First Examination will in future years be held in June and December and the Second Examination in May and November.

The fees for examination are:—First Examination, first admission 8 guineas, and for each re-admission 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 20 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First and Second Examinations of the English Conjoint Board, of the equivalent examinations in his University, on the production of certificates of attendance upon certain prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

The Primary examination is held quarterly in two parts. Part I. Elementary Biology; Chemistry, Chemical Physics; Practical Chemistry; and Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the vent of the candidate having previously passed ι one.

The Final examination is held monthly except in eptember. Part I. Clinical Surgery: Principles and ractice of Surgery, Surgical Pathology, and Surgical natomy, Operative Manipulation, Instruments, and ppliances. Part II. Clinical Medicine: Medicine, harmacology, Pathology, and Morbid Histology; orensic Medicine, Hygiene, Theory and Practice of accination; and Mental Diseases. Part III. includes idwifery, Gynæcology, and Diseases of New-born hildren and the Use of Obstetric Instruments and ppliances.

The course of study for the *Final examination*, ıcludes attendance on the Surgical and Medical ractice, with Post-mortem Examinations, at a ɔspital connected with a medical school for a period two winter and two summer sessions, including a ɔurse of Practical Midwifery, with attendance on 20 idwifery cases. The course of medical study must ktend over five years, and the offices of dresser or inical clerk must be held at a hospital or other stitution recognised by the Society. Two years ust elapse after a candidate has passed the examinaon in Anatomy and Physiology before sitting for any art of the Final examination.

Evidence shall also be given of practical instruction Infectious Diseases and in Mental Diseases (at a natic asylum or in the wards of an institution conining a special ward set apart for the treatment of ental diseases), and in any two of the following ıbjects: Ophthalmic Surgery, Laryngology with hinology and Otology, Dermatology, and Diseases Children. Candidates intending to present themlves for examination are required to give 14 days' otice. The fee for the Licence is 20 guineas. Female ındidates are admitted to examinations. The examiation offices are open from 10 A.M. to 4 P.M.; on aturdays from 10 A.M. to 1 P.M. All letters should be ldressed to the Secretary, Court of Examiners, ɔciety of Apothecaries of London, Blackfriars, E.C. 4.

ETROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical udent and medical graduate facilities for different rms of instruction and clinical observation. In each ıse further information can be obtained from the cretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses three ɔspitals—the *Dreadnought* Hospital at Greenwich, 0 beds, and the Branch Hospital in the Royal ictoria and Albert Docks, E., 50 beds; the Hospital r Tropical Diseases, Endsleigh-gardens, 50 beds, ɔndon, N.W. 1; King George's Sanatorium for ilors, Bramshott, Hants, 80 beds, and the Angas ome, 30 beds. It has also a Dispensary in the East dia Dock-road from which patients are transferred the hospitals. The London School of Tropical edicine is attached to the Hospital for Tropical seases. Sessions commence approximately pt. 25th, Jan. 9th, and July 24th. Students must qualified Medical Practitioners or be in the fifth ar of their medical studies. Accommodation for 0 Students. Fully equipped Laboratories are proled for the study of Entomology, Helminthology, otozoology, and General Medical Zoology.

In conjunction with the Fellowship of Medicine rangements have been made for a short course stributed over four weeks. Secretary: Sir P. J. chelli, C.M.G.

WEST LONDON HOSPITAL, Hammersmith, W. 6.—ıis hospital has 159 beds, all of which are constantly use. 2319 in-patients and 36,374 out-patients, ıose attendances numbered 182,697, were treated st year. Attached to the hospital is the West ɔndon Post-Graduate College. The practice of the spital is reserved exclusively for qualified men, no ıior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology. The fees for hospital practice, including lectures, are £4 4*s.* for one month, £9 9*s.* for three months, or £22 1*s.* for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Dr. Arthur Saunders, at the Hospital. Secretary of the Post-graduate College: Mr. C. Cole. Secretary of the Hospital: Mr. H. A. Madge.

ROYAL NORTHERN HOSPITAL, Holloway-road, N. 7.—This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the honorary staff there are six anæsthetists, pathologist, resident medical officer, two resident house physicians three resident house surgeons, and resident casualty officer. The hospital contains 210 beds, which are fully occupied. There is also a ward for children under five years of age. The large rectangular and circular wards, each of which contains 25 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. There is also a well-appointed physiotherapeutic department. The pathological department has been extended and is under the control of a Director of Clinical Pathology. The Reckitt Convalescent Home at Clacton-on-Sea belongs to the Hospital. It contains 30 beds. Special departments have also been established for the treatment of tuberculosis and venereal diseases. A Hospital of Recovery containing 60 beds has now been established at "Grovelands," Southgate, patients being removed from the main hospital by ambulance five or six days after operation. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patients departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office.

Special Departments.—During the past year special departments have been created in genito-urinary and neurological diseases and a fracture department.

Post-graduate Facilities.—In association with the Fellowship of Medicine two-week "refresher" courses have been arranged for March, July, and November in each year. These will include teaching in general medicine and surgery, and special lectures and demonstrations in special subjects.

Further particulars from the Secretary of the Medical Committee at the Hospital.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. 15.—This hospital is in the midst of a densely populated neighbourhood and contains medical, surgical, gynæcological, and children's wards, having 125 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, plastic surgery, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and outpatient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are four resident medical officers, and clinical assistants are appointed under certain conditions. A special intensive post-graduate course will be held in the autumn. Further particulars in regard to the hospital may be obtained from Mr. E. Gillespie, Secretary to the Medical Committee, 24, Weymouth-street, W. 1; or from Dr. J. B. Banister, Dean of North-East London Post-Graduate College, 39, Harley-street, W. 1.

London Temperance Hospital, Hampstead-road, N.W. (Established 1873; Incorporated 1917).—The hospital contains 120 beds. The in-patients in 1922 were 1059, and the out-patients and casualties numbered 13,141 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Mondays at 2 p.m., Tuesdays, Wednesdays, Thursdays, and Fridays at 9 a.m.

Hampstead General and North-West London Hospital.—The Hampstead General Hospital (Haverstock-hill) and the North-West London Hospital (formerly at Kentish Town) have been amalgamated since 1907. The Hampstead General Hospital (128 beds—viz., 102 free, 6 isolation, &c., and 20 paying or contributory) accommodates the in-patients from the districts hitherto served by both hospitals. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients department, Bayham-street, Camden Town. Further particulars from the Secretary at the hospital.

South London Hospital for Women, South Side, Clapham Common, S.W.; Out-patient Department: 86-90, Newington Causeway, S.E.—This hospital, officered entirely by medical women, is a general hospital for women, girls, and small children of both sexes, and provides accommodation for 80 patients. All diseases are treated with the exception of acute infectious fevers and mental disease. There are Ophthalmic, X ray and Electrical, Pathological, Physio-Therapeutic, and Dental Departments. The hospital is a centre for the treatment of venereal diseases under the Public Health (Venereal Diseases) Regulations, 1916. The provision of additional facilities for post-graduate training for medical women is one of the special objects of the hospital. The number of in-patients treated during the year 1922 was 1187. At the Out-patient Department in Newington Causeway 8275 new cases were treated during the past year, the total number of out-patient attendances amounting to 32,045. Clinical assistants (qualified women only) are from time to time appointed in the Out-patient Department. Two resident students act as clinical clerks in the surgical wards. Secretary: Miss M. E. Ridler.

French Hospital and Dispensary, Shaftesbury-avenue, W.C.—This hospital, which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language, has 74 beds. The Convalescent Home and Retreat for Aged French People at Brighton contains 61 beds. Secretary: Mr. G. Pondepeyre.

Italian Hospital, Queen-square, W.C.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 50 beds.

German Hospital, Dalston, E. 8.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for others in cases of emergency and accident. It has 138 beds and a sanatorium with 10 beds.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury, W.C.—The hospital, with the Finchley branch, and branches in Bloomsbury and Clapham Park, contains 265 beds and cots. The out-patient physicians attend every Monday, Tuesday, Thursday, and Friday at 2 p.m., and the physicians daily. Clinical clerks are appointed under physicians and clinical assistants to out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held three times every year, usually commencing in January, May, and October and lasting eight weeks. Special Courses in Neurological Ophthalmology, Neuro-Pathology, and the Anatomy and Physiology of the Nervous System are given. The Pathological Laboratory is available for special work under the Pathologist. The hospital has been recognised by the Conjoint Board of England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, hospital practice, and fees should be addressed to the Secretary at the hospital.

Hospital for Epilepsy and Paralysis, &c., Maida Vale, W. (85 beds).—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. Secretary and General Superintendent: Mr. H. W. Burleigh. The out-patient department is open every week-day except Saturday at 2 p.m.

West End Hospital for Nervous Diseases.—Out-patient Department, 73, Welbeck-street, W. 1; In-patient Department, Gloucester Gate, Regent's Park, N.W.; 72 beds, over 42,000 Out-patient attendances. A Pathological Department is now installed and further improvements are to be carried out in the summer vacation. A series of clinical demonstrations, apart from the general practice of the hospital, is held regularly each session and the hospital is coöperating with the Fellowship of Medicine in the programme of special post-graduate teaching organised by the Association. The Savill Memorial Prize (value £15) and Medal are offered annually for competition among post-graduate and undergraduate students who have attended at the hospital. For further particulars apply to C. C. Worster-Drought, M.D. (Dean), or to J. P. Wetenhall, B.A. (Oxon.), Secretary, 73, Welbeck-street, W. 1.

Bethlem Royal Hospital, St. George's-road, S.E. —This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They are permitted to reside in the hospital for a term generally not exceeding six months, commencing May 1st and Nov. 1st, and are provided with apartments, complete board, attendance, laundry, and a salary at the rate of £100 per annum. They are under the direction of the Physician Superintendent and are elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive clinical instruction in the wards of the hospital and qualified practitioners and other students may attend for a period of three months on payment of a fee. A Department for Nervous Diseases has been instituted in a building quite apart from the main hospital. Neurological and early mental cases are dealt with. A Course of Lectures and Practical Instruction for the Diploma in Psychological Medicine granted by the various Universities, will commence in the middle of September. For particulars apply to the Physician Superintendent.

Hospital for Consumption and Diseases of the Chest, Brompton.—The hospital contains 333 beds. The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six house physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. An additional month may be spent at the Sanatorium. Pupils are admitted to the practice of the hospital: terms £1 1*s.* for one month; three months, £2 2*s.* Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical assistants are appointed to the physicians in the out-patient department and clinical clerks to the hysicians in the wards. The hospital has been ecognised by the Conjoint Board for England as a lace where six months of the fifth year may be spent clinical work. The medical practice of the hospital also recognised by the University of London, the pothecaries' Society, and the Army and Navy and ıdian Medical Boards. Dean of the Medical School: r. L. S. Burrell, from whom particulars of lectures, inical appointments, and hospital practice can be ɔtained.

City of London Hospital for Diseases of the eart and Lungs, Victoria Park, E. 2.—During the ıst year 1201 in-patients have been treated in ıe wards. The out-patients treated during 1922 ımbered 9951. Special Departments: Surgical, aryngological, X ray, Electro-Cardiographic. Assist-ıts are appointed to the Clinics, and a limited number research workers to the Pathological Department. he In-patient staff visit generally in the afternoon, ıd welcome medical practitioners; Out-patients at P.M. Graduates desiring Assistantships in any partment should apply to the head of the Department. Physicians to In-patients: W. J. Hadley, H. Colbeck, Clive Riviere, A. G. Levy, A. J. Scott-nchin, F. G. Chandler; Surgeon: W. H. C. Romanis; aryngologist: W. G. Howarth; Physicians to Out-ıtients: Sir Percy W. Bassett-Smith, J. B. Alexander, B. Christopherson; Electro-Cardiographic Department: Dr. A. J. Scott-Pinchin; Radiologist: Dudley Stone; Pathologist: S. R. Gloyne. Tuberculosis spensary (Boroughs of Bethnal Green and part ackney) Tuberculosis Officers: H. T. Howell and W. Hamilton. Other information from the Secre-ry of the Hospital.

Royal Chest Hospital (for all affections of the art and lungs), City-road, E.C. (80 beds). Branch the Royal Northern Hospital, Holloway.—This spital provides accommodation for 80 in-patients. cpenditure for 1922 £15,068, income £11,476. The tendance of out-patients averages 30,000 annually. cretary: Mr. G. G. Panter.

The Mount Vernon Hospital for Tuberculosis D Diseases of the Lungs and Heart, North-ood, Central Out-patient Department, Fitzroy-uare, W.—The hospital contains 157 beds, Medical d Surgical; 50 beds reserved for children requiring rgical aid. Number of in-patients, 473; out-tients, 2024. Resident Medical Staff. Clinical monstrations are given by the Visiting Medical aff at the hospital at Northwood. Clinical assistants appointed to physicians in the wards and in the t-patient department. Secretary: Mr. W. J. Morton.

Queen Charlotte's Lying-in Hospital and dwifery Training School, Marylebone-road, W.—This hospital receives about 2000 patients nually, besides having a large out-patient depart-nt. Medical pupils are received at all times of the ar. Pupils have unusual opportunities of seeing stetric complications and operative midwifery, on ount of the very large number of primiparous es—nearly one-half of the total admissions. nical instruction is given on the more important es which present themselves. They also receive uable instruction in the Ante-natal Department, ere over 4000 patients attend yearly. Special cture-demonstrations are given by members of the ff. Certificates of attendance at this hospital are ognised by all the Universities, Colleges, and licens-bodies. Pupil midwives and monthly nurses are eived and specially trained. A Residential College vides accommodation for five men at a time, dents and qualified practitioners, and is opposite hospital, with which it is in telephonic communi-ion. Arrangements have been made for Medical ıdents to receive the preliminary instruction in ıctical Midwifery recommended by the General dical Council. Women students are received. further particulars application should be made to Arthur Watts, Secretary, at the hospital.

Hospital for Women, Soho-square, W.—The teaching in connexion with the above hospital has been greatly extended, and is available for Post-Graduates only, in limited numbers. Every facility is afforded them, by the teaching staff, of obtaining experience in diagnosis and treatment of Gynæcological diseases. The hospital contains 68 beds, and the out-patient attendances are over 14,000 per annum. Operations take place daily at 2 o'clock except on Saturdays. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can also be gained in the treatment of malignant disease by means of radium. Incorporated with the hospital is the London School of Gynæcology, comprising attendance in Out-patient Department, operating theatre, clinical lectures, and X ray treatment. For further particulars apply to the Secretary.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. The fees, payable in advance, are £3 3*s.* for three months. Full particulars may be obtained on application to the Secretary at the hospital. There are 70 beds. Secretary: Mr. G. H. Hawkins.

East London Hospital for Children and Dispensary for Women, Glamis-road, Shadwell, E. —The hospital maintains 130 cots, and on an average 245 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to Mr. W. M. Wilcox, the Secretary.

The Hospital for Sick Children, Great Ormond-street, W.C. 1, contains 244 beds. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to six medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Fees for hospital practice, one month, £2 2*s.*; three months, 5 guineas; perpetual ticket, 10 guineas. Clinical Clerks, 1 guinea for one month. Ophthalmological Clerkships.—Clinical Clerks are appointed once a month. Fees £1 1*s.* for one month's attendance. Pathological Clerkships.—Facilities are afforded for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology in the Pathological Laboratories. Clerks attend for about four hours daily. Fees: For one month, £3 3*s.*; for two months, £5 5*s.*; for three months, £6 6*s.* A reduction is made in the case of those already holding tickets for general attendance at the hospital. Time so spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, and by the Conjoint Board for England as part of the approved curriculum for students entering for a final examination. These appointments are open to students of all recognised medical schools. In addition, special lectures in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily. Details may be obtained by application to the Dean or Secretary at the hospital. The medical school is a constituent part of the new London Post-Graduate Association. Secretary: Mr. James McKay.

Evelina Hospital for Sick Children,* Southwark Bridge-road, S.E.—This hospital contains 76 cots and a very extensive Out-patient Department. About ten clinical assistants (either sex), to work with the Honorary Medical Staff for Out-patients, are appointed quarterly for a period of three months; there is no salary attached to these posts: but, on the other hand, no fees are charged.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—The hospital contains 130 beds and has a large out-patient department (over 1400 weekly); the home at Broadstairs has 50 beds. Out-patients are seen as under:—Diseases of the Eye: Tuesday, 2 p.m. Diseases of the Skin: Monday, 1.45 p.m. Whooping-cough Cases: Friday, 2 p.m. Dental Cases: Thursday, 1.30 p.m. Medical and Surgical Cases: Mornings at 9.30 and 11.30. Accidents and urgent cases are admitted at any time. Secretary: Mr. D. St. John Bamford.

A Private Nursing Home for Children is now open at 29, Tite-street, in connexion with and adjacent to the hospital. Terms: £1 1*s.* per day or £5 5*s.* per week. Application for admission should be made to the Secretary. Patients must be under the care of a consultant of one of the hospitals of London, and the question of payment for his fees is a matter of arrangement between him and the child's parents.

Queen's Hospital for Children (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E. 2. (Telephone 305 and 534 Dalston.) For the sick children of the poor under 14 years of age. Established 1867. 134 beds in London and 36 at the seaside branch, "Little Folks" Home, Bexhill.—During the past year 1878 in-patients and 43,647 out-patients (attendance 115,027) were received. The surgeons attend on Tuesdays at 9.30 a.m. and Wednesdays and Fridays at 1.45 p.m.; the physicians daily at 1.45 p.m., except Saturday, and Wednesday and Friday, 9.30 a.m., as well as 1.45 p.m. Whooping-cough Physician: Saturday, 9.30 a.m. The practice of the hospital is open to students by arrangement with the medical staff. Clinical demonstrations open to medical practitioners and students of medicine will be announced in the medical journals. Applications should be made to the Secretary, Mr. T. Glenton-Kerr.

Belgrave Hospital for Children, Clapham-road, S.W.—Clinical Assistants (men or women) are from time to time appointed to the members of the Visiting Staff attending in the Out-patient Department at this hospital, and facilities are given for attendance in the wards.

Alexandra Hospital for Children with Hip Disease (late of Queen-square, W.C.), Kettlewell Home, Swanley, Kent (in connexion with St. Bartholomew's Hospital).—At this hospital cases of hip-disease, spinal caries, and tuberculous diseases of other bones and joints are treated. Students who have obtained a recommendation from their teachers can attend to see the practice. In-patients, Swanley, Kent; Out-patients, St. Bartholomew's Hospital; Fridays, 1.30 p.m. Apply for particulars to the Dean of the Medical College, St. Bartholomew's Hospital, London, E.C. 1.

Royal London Ophthalmic Hospital (Moorfields, 1804–1899), City-road, E.C. 138 beds.—This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. Last year there were 2614 in-patients, the out-patients were 47,532 of whom 40,735 were new out-patients, and the attendances were 117,120. Operations are performed daily from 10 a.m. to 1 p.m., and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3*s.*; perpetual, £5 5*s.* Special courses of instruction, which extend over a period of five months, are given by members of the Surgical Staff; beginning in October and March. A composition fee of 24 guineas (£25 4*s.*) will entitle students to a perpetual ticket, and will admit them once to all the lectures and classes and to the examination for the hospital's full certificate. A special course is also held in the preliminary subjects (Anatomy, Physiology, and Optics) for the various degrees in Ophthalmology. The fee for this course is 12 guineas. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary Superintendent.

Royal Westminster Ophthalmic Hospital, King William-street (next door to Charing Cross Hospital), Strand, W.C. 2.—The hospital contains 42 beds. Out-patients, who number over 14,000 annually, are seen daily at 1 p.m., and operations are performed in the theatre at 3 p.m. The practice of the hospital is open to both men and women practitioners and students. Clinical evenings, at which interesting cases are shown and discussed, are held twice each term at 8 p.m. on the second Tuesday of the month. In addition to the ordinary clinical instruction, a systematic course of Lectures and Practical Classes commences in October and May. Lectures in this course are given daily (except on Saturday) at 4.30 p.m., including all subjects required by candidates for the D.O.M.S., R.C.P. & S. Eng., Part II., and practical instruction is given in Operative Surgery and Ophthalmic Pathology and Bacteriology. A corneal microscope has recently been purchased and instruction in the Microscopy of the Living Eye can now be obtained. Fees: One month, £1 1*s.*; three months, £2 2*s.*; six months, £3 3*s.*; perpetual, £5 5*s.*; composition fee for perpetual ticket and attendance at classes (except Operative Surgery and Pathology, for which fee in each case is £2 2*s.* per course), £10 10*s.* Students of the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant, and senior or junior clinical assistant. Full details can be obtained on application to the Dean.

Royal Eye Hospital, St. George's-circus, Southwark, S.E. 1.—There are 40 beds and 2 cots. In 1922 there were 50,911 attendances in the Out-patient Department, the new patients being 20,923. The daily average of attendances was 169 patients. In-patient admissions numbered 946. Clinical instruction is given to students and post-graduates daily at 2.30 p.m., and Lectures, Demonstrations, and Laboratory Classes are arranged in preparation for examinations in Ophthalmology. Post-graduate students are eligible for appointment as Clinical Assistants and as Refraction Officers. Dean: Mr. A. D. Griffith.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—This hospital has 40 beds and clinical teaching is given daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on refraction and other subjects, to meet the requirements of the Conjoint Board for the D.O.M.S., and of the University of London for the M.S. in Ophthalmology, are given during the winter months, commencing in October. The out-patient work begins at 1 o'clock, and operations are performed daily between 2 and 4 o'clock. This school is recognised as a teaching institution by the Universities of London and Oxford, and the Conjoint Board of the Royal Colleges of Surgeons and Physicians. The school has also undertaken to receive a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. Secretary: H. R. S. Druce.

---

* No returns.

Western Ophthalmic Hospital, Marylebone-road, .W.—16 beds. Out-patient attendances, 30,264. oth In-patient and Out-patient Departments of this ospital are open to medical graduates. Fees £1 1*s.* per ree months. Honorary Secretary: H. W. Burleigh.

Irrigations for males are given daily 8 to 10 P.M. For females Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays at 11 A.M. to 1 P.M., at 91, Dean-street. The next Special Course of Lectures will be held in October. Secretary, Henry J. Eason, Head Office, 283, Harrow-road, W. 9.

ENGLISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

Under this heading we include all the hospitals which are recognised by the English Royal Colleges for a part of the required attendance on medical and surgical practice, for medical clerkships, and surgical dresserships. The list includes nearly every hospital of a general character in the country having more than 150 beds, though occasionally a large hospital is omitted because equally good opportunities are afforded to students at other institutions in its neighbourhood, while a small hospital may be included because no such facilities for study are present elsewhere. The list is arranged alphabetically as to the town where the hospital is located. Most of the larger general hospitals of the kingdom have already been noticed in connexion with the Universities.

Bath Royal United Hospital, Bath.—This hospital contains 134 beds, and possesses X ray, Massage, Bacteriological Departments, a new Pathological Laboratory, and a fine library. Secretary: Mr. J. M. Sheppard. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men), from 5 to 7 P.M., and Ear, Throat, and Nose Clinics on Thursdays, at 4 P.M.

Bedford County Hospital, Bedford.—This hospital has 100 beds, with X ray and Pathological Departments, paying wards for 15 beds, and a convalescent home (20 beds) at Aspley Heath, near Woburn Sands, in connexion with the institution. The hospital is approved by the University of London for the purposes of the M.D. and M.S. Examinations. Secretary: Mr. Beauchamp Wadmore.

Bradford Royal Infirmary, Bradford. — This hospital contains 215 beds. The material passing through the surgical wards consists of major operations, chiefly abdominal, and gynæcological work, and affords excellent facilities for either students or post-graduates. There are special clinics for Orthopædic and Venereal cases. Plans for a new hospital of 382 beds have been adopted, and building operations will be commenced as soon as funds will allow.

Royal Sussex County Hospital, Brighton (225 beds).—This hospital affords ample facilities for students, possessing a large out-patient department, including Ophthalmic, Dental, Dermatological, Gynæcological, X ray, and Orthopædic sections, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years, on payment in advance of a fee, not exceeding 20 guineas, as the Board of Management shall direct.

Kent and Canterbury General Hospital, Canterbury.—The hospital contains 115 beds. Pupils of the staff are admitted to the practice of the hospital. Operations four days of the week. There is an Ophthalmic Department with two wards for in-patients, a Venereal Clinic, an Orthopædic Department, &c. Secretary, Mr. F. P. Carroll.

Coventry and Warwickshire Hospital, Coventry (established 1840).—This hospital contains 241 beds, and a new wing as well as theatre and kitchens have been added. Special clinics are held for diseases of the Eyes, Ears, Nose and Throat; Gynæcology; X ray and Electrical Treatment. There are also V.D. Clinics. Clinical students are received, and there are paying wards. Secretary: Miss R. Hooper.

Derbyshire Royal Infirmary, Derby.—This hospital contains 320 beds. It was founded in 1810, and was entirely rebuilt and enlarged 1892–1915 on the most modern lines at a cost of over £144,000. There is a separate ophthalmic block of 33 beds, a separate children's block of 34 beds, and a special department for gynæcological cases. There are four resident house surgeons, a resident house physician, and an assistant house surgeon and casualty officer. There are also well-equipped orthopædic, X ray, electrical, and venereal diseases departments. Registered medical students are admitted to witness the medical and surgical practice on payment of 10 guineas annually.

Royal Devon and Exeter Hospital, Exeter.—The hospital contains 225 beds (including special children's wards) and has a good library, museum, post-mortem room, and pathological laboratory. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897 and the "Victory" wing for the treatment of discharged disabled soldiers and sailors completed and opened in 1922. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). The Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King. A department was opened in 1917 for the treatment of genito-urinary diseases; there are three sessions per week, two for men at 3 P.M. and 7 P.M., and one for women at 3 P.M.

West of England Eye Infirmary, Exeter.—Secretary: Mr. W. W. Beer. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1922, 3288. A ward is set aside for newly-born babies suffering from infectious eye diseases. The mothers are accommodated with their babies.

Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—This hospital, which was granted the title of "Royal" on the occasion of King Edward VII.'s visit to Gloucester in the year 1909, has 140 beds. Secretary: G. Hurford. In-patients, 1526; out-patients, 8281. An electrical and massage department has been established and venereal clinic opened. Also ear, nose and throat department and X ray Department.

North Staffordshire Infirmary, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for about 304 patients, including Children's wards, and a special department for the treatment of Diseases of the Eye, a special X Ray and Electrical Department, a special department for the treatment of Diseases of the Ear, Nose, and Throat, a special orthopædic department, and venereal diseases clinics, so that there are excellent facilities for acquiring a practical knowledge of the profession. During the last six years the sum of £35,000 has been spent on new buildings and alterations. A new Out-patient Department, costing £12,000, a new Children's Ward of 30 beds, a new Pathological Department, and a second large Operation Theatre are amongst the structural improvements already completed. The whole institution is now equipped in a thoroughly up-to-date manner. Secretary and House Governor: Mr. W. Stevenson.

Hull Royal Infirmary, Hull.—This Hospital contains 266 beds, and since its establishment in 1782 until the erection of the circular wards in 1907 has undergone steady additions and improvements, including an up-to-date pathological department recently added. A branch convalescent home at Withernsea is a special feature of the charity.

Leicester Royal Infirmary, Leicester.—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 233 beds, and at the Children's Hospital in connexion 70; venereal diseases, 17; total 320. A new wing containing 100 beds is in course of construction. A reconstruction scheme has been carried out, and £200,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, and self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Open-air balconies on all three floors are a feature. A central sterilising department has been provided. Pathological Laboratories and post-mortem rooms have recently been opened at a cost of £11,000, also an orthopædic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home has recently undergone enlargement by 60 bedrooms. The 150th anniversary of the Institution has recently passed and an effort is being made to raise a sum of £100,000 a commemoration. Funds are being raised for the oundation of a City University, and a splendid site vas presented by the late Mr. T. Fielding Johnson, .P., an ex-chairman of the Royal Infirmary. There re eight resident salaried medical officers at the Infirmry—viz., four house surgeons, one house physician, ne assistant house physician, and two dressers. he posts are usually filled half-yearly and afford xceptional opportunities for post-graduate experience nd senior students. Dressers are given an honorarium. tudents are encouraged to make full use of the facilities hich exist to gain clinical knowledge in the wards. he hon. medical and surgical staff are wishful of fording instruction in a variety of conditions which n active and well-equipped general hospital in a large ommercial centre is called upon to treat. A new esidency for Doctors is in course of erection. Chairan of the Board: Mr. T. Fielding Johnson, J.P. eputy Chairman of the Board: Mr. C. J. Bond, .M.G., F.R.C.S. House Governor and Secretary: r. Harry Johnson, from whom information as to rospective vacancies on the Resident Staff may be btained.

NORTHAMPTON GENERAL HOSPITAL, Northampton. –Two new wings were opened in 1904 and the old uildings entirely renovated and rearranged. The umber of beds is 231, 34 of which are occupied by ischarged disabled pensioners. Non-resident pupils eceived and have every opportunity of acquiring a ractical knowledge of their profession. The fee is 10 10*s.* Pupils can be received at any time. An p-to-date Pathological Laboratory has recently been rected.

NORFOLK AND NORWICH HOSPITAL, Norwich.—This ospital has at present 300 beds. There is a convalesent home at Cromer. Students are admitted to the ractice of the Hospital for a fee of £5 5*s.* for six onths. Secretary: Mr. Frank Inch.

NOTTINGHAM GENERAL HOSPITAL.—There are at is hospital 310 beds available for medical and rgical patients, and 46 beds are in the detached ard known as "The Cedars" Convalescent Hosital. The Medical and Surgical Staffs consist f two Honorary Consulting Physicians; 2 Honorary onsulting Surgeons, 1 Honorary Consulting hysician in Venereal Diseases; 3 Honorary hysicians; 4 Honorary Surgeons; 2 Honorary ssistant Physicians; 2 Honorary Assistant Surgeons; Honorary Aural Surgeons; 1 Honorary Dermatoloist; 2 Honorary Anæsthetists; 1 Honorary Surgeon entist and 1 Honorary Medical Officer in Charge of ray and Electro-therapeutic department. The esident Medical Staff consists of 2 House Physicians, House Surgeons and 1 Casualty Officer. The special epartments are the Ear, Nose and Throat, Skin, ental, Massage and Exercise, X ray, Orthopædic, lectro-therapeutic. House Governor and Secretary: r. P. M. MacColl. II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course of instruction in Practical Midwifery and have personally conducted at least 12 cases of labour.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teacher as may be recognised for the purpose by the University Court. Of the subjects of study—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than one-half must be taken in the University of Edinburgh, which corresponds to the two years above referred to.

Women are admitted to graduation in medicine under the same conditions as men.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £34 13*s.*, and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £9 9*s.*; for the Second Division (Anatomy and Physiology), £7 7*s.*; for the Third Division (Pathology and Materia Medica and Therapeutics), £6 6*s.*; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Gynæcology, and Forensic Medicine and Public Health), £11 11*s.*

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £21, and the fee to be paid for the degree of Ch.M. is £21.

Post-Graduate Instruction.—Courses of instruction are given for the Degrees of B.Sc. and D.Sc. in Public Health and for the University Diplomas in Public Health, Tropical Medicine and Hygiene, and Psychiatry. These Diplomas are open to approved registered practitioners as well as to graduates in Medicine and Surgery of the University. The University also takes part in the Courses given under the auspices of the Edinburgh Post-Graduate Courses in Medicine. In the departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for candidates for the Degree of Ph.D. whose applications to engage in research have been accepted by the Senatus.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars can be obtained from the Dean of the Medical Faculty.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The practical classes and laboratories will open and the lectures commence on Oct. 9th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Special courses of instruction for dental students are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £170, payment of which is distributed over the period of study. There is no composition fee.

Further particulars regarding the school, also its calendar (price 6*d.*) may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

In connexion with the University and Royal Colleges Post-Graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Clinical Instruction.—ROYAL INFIRMARY, Edinburgh.—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medico-Electrical and X Ray Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student to a life ticket. The appointments are as follows: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH (with which is incorporated the Edinburgh Eye Dispensary), 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time. A post-graduate course in Diseases of the Ear, Nose, and Throat is held each academic term, commencing Oct. 16th, Jan. 14th, and May 8th. The class meets at 5 P.M. each Tuesday and Friday, and the instruction, which is essentially practical, is supplemented by lantern demonstrations. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Secretary: Mr. J. P. Watson, W.S., 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; B.Sc. in Pharmacy; and Ph.D. in the Faculty of Medicine.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases Peculiar to Women and to Infants.

The degrees of M.D. (*Doctor of Medicine*) *and Ch.M.* (*Master of Surgery*) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College and must prosecute a course of special study or research for two or three years and give evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject-matter of the thesis.

In 1919 new chairs were instituted in Bacteriology, Organic Chemistry, and Physiological Chemistry.

Fees.—The Fees for M.B. and Ch.B. are £34 13*s.* The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3*s.*, £4 4*s.*, or £6 6*s.*, and the present fee for hospital attendance is £7. The fee for M.D. is £21, and for Ch.M. £21.

The great majority of the students take their hospital course at the Western, Royal, and Victoria Infirmary, and at the district hospitals of the Glasgow Parish Council, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, Insanity, and Electro-diagnosis and Therapeutics. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students mostly attend the Royal Infirmary.

Post-graduate Medical Teaching.—Organised Post-graduate Medical Teaching is now available in Glasgow under the auspices of Glasgow Post-graduate Medical Association. This Association is composed of practically all the Teaching Institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a Board elected periodically by them. The chairman of the Board is Principal Sir Donald MacAlister, and the vice-chairman Sir Hector C. Cameron. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from Dr. John N. Cruickshank, Secretary, Post-Graduate Medical Association, University, Glasgow.

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course. A full list will be found in the University Calendar.

THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.—Courses are given which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Dental Hospital, Glasgow.

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men.

The Carnegie Trust extends its benefactions to students of the Anderson College of Medicine. Full particulars may be obtained from Sir W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Hugh Cameron, M.A., F.E.I.S., Educational Institute Office, 34, North Bridge-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Walter Hurst, Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

The Winter Session will open on Monday, Oct. 8th, 1923.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The classes in St. Mungo's College qualify for the medical qualifications of the English, Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. The classes are open to male and female students equally. The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £120. Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

QUEEN MARGARET COLLEGE (Women's Department of the University).—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University. Over 500 women have now taken the degree of M.B., C.M., or M.B., Ch.B. of the University of Glasgow and 30 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill, Queen Margaret College, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Excellent facilities for clinical work are given in the Royal Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. The Winter Session will open on Oct. 8th. New students of Medicine will be admitted in April, 1924. Applications for entrance at that date should be made before Feb. 1st, 1924.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. St. Mungo's College is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, skin, venereal diseases, burns and septic cases. The wards are open to Women Students. At the Out-door Department the attendances in 1922 numbered over 180,000. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 11 house surgeons, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Classes are held during September in Clinical Medicine, Clinical Surgery, Clinical Gynæcology, Diseases of the Skin, Venereal Disease in the Male, Diseases of the Throat, Nose and Ear, and in Diseases of the Eye. For information regarding fees and other particulars, application should be made to the Superintendent.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 600. Special wards are set apart for

Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Teeth, Skin, Venereal Disease, and Electro-therapeutics. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course. The fees are as follows:—For Infirmary Attendance, Dispensary, &c.: (*a*) For Perpetual Ticket, £12 12*s.*; (*b*) for Single Term Ticket, £1 11*s.* 6*d.* For Courses of Instruction: (*a*) Six Months or Two Terms, £5 5*s.*; (*b*) Three Months or One Term, £2 12*s.* 6*d.* A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods. Secretary: J. Matheson Johnston, C.A., 87, Union-street.

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics.

Royal Hospital for Sick Children, Yorkhill, Glasgow.—This institution, which was founded in 1882, consists of: (1) a hospital at Yorkhill containing 270 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 30 cots, opened in 1903. Children treated must not be over 13 years of age, nor suffer from infectious diseases. At the hospital about 5000 in-patients are treated annually in the wards and about 13,000 out-patients are treated. There are two lectureships in the University of Glasgow in connexion with the hospital, one on the Medical Diseases of Infancy and Childhood, and the other on Surgery and Orthopædics in Relation to Infancy and Childhood. These lectureships are held by the Visiting Physician, Dr. Leonard Findlay, and one of the Visiting Surgeons, Mr. Alex. MacLennan. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition special facilities are given for post-graduate study. Information with regard to clinical instruction, lectures, demonstrations, post-graduate study, &c., may be obtained from the Med. Superintendent.

The Glasgow Royal Maternity and Women's Hospital, Rottenrow.—The new hospital, which was opened in 1908, is in point of size the largest of its kind in Britain and has accommodation for 108 patients. A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Ante-natal Department and an Infant Consultation Clinic. In 1922 4951 normal cases and 2447 abnormal cases were treated by the hospital in the In-door and Out-door Departments. Secretary: Mr. William Guy, 146, Buchanan-street. Full particulars as to fees and accommodation may be obtained from the House Superintendent at the hospital.

Royal Samaritan Hospital for Women, Glasgow.—This hospital, founded in 1886, is the largest purely gynæcological hospital in Great Britain, possessing, as it does, over 90 beds, which will be increased to 160 when building extensions are completed. It offers excellent facilities for clinical instruction in the diseases peculiar to women, treating in the wards and in the out-patient department from 5000 to 6000 cases per annum. Lectures and clinical demonstrations are given by members of the surgical staff to students and to post-graduates; and the hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for co-ordinating post-graduate medical teaching in all the hospitals. For further information application may be made at the Hospital, or to T. Mason Macquaker, M.A., B.L., Secretary, 149, St. Vincent-street, Glasgow.

Glasgow Lock Hospital, 41, Rottenrow.—The hospital contains 83 beds. During 1922 373 patients were admitted to the wards; 19,725 visits were made by out-door patients at the dispensary. A Labour Ward has been added. Classes are held for the clinical instruction of medical students. These classes are now compulsory, and 120 students attended last year. There are also post-graduate classes held. J. Neilson Gray, LL.B., secretary and treasurer, 65, Bath-street, Glasgow.

Glasgow Ophthalmic Institution, 126, West Regent-street, and 131, Wellington-street (30 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 778; out- or dispensary patients, 12,524; daily average of attendances, 127·5; total attendances, 35,434. Operations on Wednesdays and Saturdays. This institution is administered by the Royal Infirmary. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

Glasgow Eye Infirmary, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 26,229 and the total number of cases in 1922 was 21,872. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October. Post-graduate Classes will be held.

Glasgow Hospital for Diseases of the Ear, Nose, and Throat, 27 and 28, Elmbank-crescent.—14 beds. New patients, 6004. Attendances at out-patient department 20,093. Admitted to in-door department 431. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School. Secretary: D. N. Mackay, 219, St. Vincent-street, Glasgow.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (L.D.S.).

The Preliminary Examination includes (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects: (α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other approved modern language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of LL.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years after registering as a medical student. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica and Pathology and Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 15 guineas, and for the degree of Master of Surgery 15 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews.

For further particulars and details as to scholarships and bursaries application should be made to Prof. Charteris, Dean of the Medical Faculty, University College, Dundee.

University College, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

Royal Infirmary, Dundee.—The Infirmary contains 408 beds. In addition to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), Diseases of Women, of Children, of Eye, of Ear, Nose and Throat, of Skin Cases, and for Clinical Pathology, Radiology, and Electro-therapeusis. An extension providing for new X Ray and Massage Departments and for additional Operation Theatre accommodation is being constructed at a cost of £20,000. Clinical teaching is given to male and female Students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the other Boards of the United Kingdom. Nine Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the Physicians and Surgeons; and Students are appointed as assistants in the pathological department. The fees for Hospital attendance are as follows: For Perpetual Ticket, £12; or if paid in instalments, £12 12*s.*; Ticket for 12 Months, £4 4*s.*; Ticket for 3 Months, £1 11*s.* 6*d.* Further information may be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.). The Degree of Doctor of Philosophy (Ph.D.) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Before commencing his medical studies each student must comply with the following regulations: (1) Every Candidate desiring admission to the Faculty of Medicine must be in possession of the necessary "Certificate of Fitness" issued and attested by the Scottish Universities Entrance Board, 81, North-street, St. Andrews. Forms on which to make application for this Certificate may be obtained from the Secretary to the University of Aberdeen. From and after Jan. 1st, 1921, the Regulations contained in the Ordinances for Degrees in Medicine are revoked, and the following General Regulation made by the Entrance Board is substituted therefor, namely: "That (*a*) the Group Certificates of the Scottish Education Department, or (*b*) the evidence of satisfactory completion in Schools in Scotland of a curriculum of Secondary Education, as attested by the said Group Certificates or otherwise, or (*c*) the Leaving or other Certificates accepted as qualifying for admission to the Universities in the case of applicants for admission from outside Scotland, which shall be deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for graduation in the Faculty of Medicine, shall be the same as those which, under the Regulations for the time being in force, are deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for graduation in the Faculty of Arts or, alternatively, in the Faculty of Science, for Degrees in Pure Science."

Candidates, therefore, before entering on the curriculum for the Degree must: (1) have passed (*a*) the Arts Preliminary Examination, or (*b*) the Science Preliminary Examination, or (2) hold a qualification recognised as exempting from such examination. (3) Have attained the age of 17 years. (4) That they have passed the Pre-registration Examination in Physics and Chemistry.

The following regulations for Pre-registration Courses in Physics and Chemistry have been made by the University of Aberdeen:—

1. Pre-registration Courses in Physics and in Chemistry will be held in the Winter Term and

in the Summer Term. The fee for each course is £2 2*s*.

2. The Senatus Academicus has power to grant exemption from attendance on these courses of instruction to students who have completed courses of instruction in Physics or Chemistry in a Secondary School, Technical or University College, Medical School or University, provided that the courses include practical work.
3. Pre-registration Examinations will be held in Marischal College at the end of the Summer Term, immediately before the commencement and at the end of the Winter Term, and at the end of the Spring Term, or at such other times as the University Court, after consultation with the Senatus Academicus, may determine. The Examination Fee is 10*s*. 6*d*. for each subject.
4. The Senatus has power to grant exemption from the Pre-registration Examination to candidates: (i.) who have passed an Examination in Physics and Chemistry for a Degree in Arts, Science, or Medicine at any University in the United Kingdom, or any other University specially recognised for the purpose by the University Court, or (ii.) who have passed an Examination in these subjects which has been previously specially recognised by the University Court as equivalent to the Examination carried out by the University of Aberdeen.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital; they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

The cost, including Matriculation, Class, Degree, and Hospital Fees, for the whole curriculum leading to the Degrees of M.B. and Ch.B. is approximately £235.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institutions, &c.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis must be presented for approval. The fee is £10 10*s*.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £160 per annum. Prizes and Medals: 13 Gold Medals and Prizes for proficiency in special departments, &c.

Clinical Instruction is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff.

ABERDEEN ROYAL MENTAL HOSPITAL.—Contains, with hospital attached to main institution and agricultural branch, about 950 beds. Clinical instruction is given to students during three months in summer. Clerk and Treasurer, Mr. A. Scott Finnie, 343, Union-street, Aberdeen.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

SCOTTISH CONJOINT BOARD.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months; Practical Physiology, three months; Materia Medica, three months; Pathology (including Practical Pathology), nine months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months; Gynæcology, one course of not less than 13 meetings; Diseases of Children, one course of not less than 13 meetings; Medical Jurisprudence and Public Health, three months. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or act for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; Gynæcology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c. The fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject.

There are four periods of examination annually: During the ensuing period thrice in Edinburgh and once in Glasgow, in 1923–24. The Registrar in Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom further particulars concerning fees can be obtained.

For students registered with the General Medical Council after Jan. 1st, 1923, more extensive Regulations are in force, and candidates applying for Regulations should state date of registration.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship.*

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence. The fee for the Membership is £36 15*s.*, 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected from the ranks of the *Members.* The fee is £64 18*s.*

ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees of diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

The Fellowship.—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly vivâ voce, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiateship of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to appear for examination must be given by the candidate to Mr. D. L. Eadie, 49, Lauriston-place, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, otherwise a special application, with six testimonials, must be made to the President and the Council of the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held as separate qualifications.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £30, £10 of which sum are returned to any successful candidate who already holds the Licence of the Faculty. An additional sum of £20 is required in the case of candidates resident within seven miles of Glasgow. In certain circumstances Fellows may be elected as a mark of distinction.

Licence.—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

The hospitals which are recognised by the Scottish Conjoint Board, as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 390) and the Irish Conjoint Board (see p. 411).

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—In order to join the School of Physic students pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 2nd.

Degrees in Medicine (*M.B.*), *Surgery* (*B.Ch.*), *and Midwifery* (*B.A.O.*).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Botany, Zoology, Physics and Practical Physics, Systematic, Descriptive and Applied Anatomy, Chemistry and Practical Chemistry, Histology, Physiology and Practical Physiology, Practice of Medicine, Midwifery and Gynæcology, Pathology and Bacteriology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Surgery and Operative Surgery; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy, Physiology, and Organic Chemistry, and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica, Hygiene and Jurisprudence, and Pathology and Bacteriology; and Part II., Medicine, including Clinical, Surgery, including Operations, Midwifery and Gynæcology, Mental Diseases, and Clinical Ophthalmology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth year.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also read and discuss a thesis before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital, a six months' course in Trinity College, and then pass a special examination.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Clinical Instruction.—The hospital facilities for clinical instruction available in Dublin will be described below.

NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres. All students must pass in five subjects (three of which must be Irish, English, and mathematics). All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other modern language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate, History and Geography (*as a composite subject*), Natural Philosophy, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology and Hygiene. Candidates who, under the regulations are exempted from the necessity of presenting Irish as one of their subjects, may present as their fifth subject either a second language or a second science subject. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, may be accepted as matriculated students of the Faculty of Medicine on passing the matriculation examination in any faculty of the University.

The medical degrees granted are:—

M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908. Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College. The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and coöpted lecturers, a body of graduate members, and a body of student members matriculated in the University. The first professors and lecturers were appointed by the Dublin Commissioners Irish Universities Act, 1908.

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland.

Universities Examinations in Medicine.—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and Materia Medica.

Degrees of M.B., B.Ch., and B.A.O.—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year when the curriculum has been completed. The course of study is as follows:—First year.—Winter: Anatomy and Practical Anatomy (required for the Second Examination), Applied Chemistry, Materia Medica and Pharmacology, Applied Anatomy and Physiology, Practical and Applied Physics (with Laboratory Course). Summer: In addition, Applied Biology, Anatomy, and Physiology. Second Year.—Winter: Anatomy, Practical Anatomy, Physiology, and Practical Physiology (physical and chemical). Summer: Anatomy, Practical Anatomy, Physiology, and Practical Histology. Third year.—Winter: Pathology, Surgery, Materia Medica and Pharmacology, Applied Anatomy and Physiology, and Pharmacy. Summer: Materia Medica and Therapeutics, and Practical Pathology. Candidates are also required to attend a General Hospital for nine months (winter and summer). Fourth year, or fourth and fifth years.—Medicine, Medical Jurisprudence and Hygiene, Midwifery and Gynæcology, Operative Surgery, Therapeutics, Applied Anatomy, and Ophthalmology and Otology. Candidates are also required to attend a General Hospital for nine months (winter and summer), and to take instruction in Vaccination, and three months Fever Hospital. Fifth year.—If the Academic (Collegiate) Courses are taken as above, the Courses of the fifth year will be the following: Hospital Attendance, General Hospital, nine months; Clinical Ophthalmology and Otology, three months; Practical Midwifery and Gynæcology, six months; Mental Diseases, to be attended at a Lunatic Asylum, three months. (*Note.*—Practical Midwifery and Gynæcology may be taken in the fourth year after the Systematic Course of Midwifery, but it must not be taken concurrently with the period of attendance at Fever Hospital.) The degree of M.D. may be obtained either by examination or on published work.

Fees.—The fees for Courses may be obtained on application to the Registrar for the College publications.

Information concerning these, and the numerous scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Prof. E. P. McLoughlin.

UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting once in each year in the Mardyke grounds.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who are candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council. For information as to the conditions and courses of the Matriculation Examination application may be made to the Registrar, National University, Dublin.

Admission of Medical Students.—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may be admitted to the rank of fourth-year students.

Residence of Students.—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, the Cork Fever Hospital, the Cork District Hospital, and the Cork Ear, Eye, and Throat Hospital.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, Professor A. E. Moore.

South Charitable Infirmary and County of Cork General Hospital (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for nine months, £12 12*s.*; for six months, £8 8*s.*; for three months, £4 4*s.* Two resident pupils will be appointed by competitive examination.

Cork North Charitable Infirmary and County and City of Cork General Hospital (112 beds).—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior students on two days weekly. Fee for perpetual ticket, £22 1*s.*; for 12 or nine months, £9 9*s.*; for six months, £5 5*s.*; and for three months, £3 3*s.* Two resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, and a special dental department. The hospital contains a fully equipped Pathological Department, and a large and extensive X ray Department has recently been added.

Mercy Hospital.—This hospital contains 130 beds (temporary addition to 160) for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical and surgical, also eye, ear, and throat attendances for 1922, 29,762: intern patients, 1733. Total extern, 29,762. Daily average, 133·6. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor.

Cork Mental Hospital (Psychological Medicine).—A course of Clinical Lectures on Mental Disease and Allied Neuroses will be delivered by the Resident Medical Superintendent in the Cork Mental Hospital as soon as possible after the opening of the Trinity Term. All Students wishing to enter for the course are expected to attend at the Asylum about that time. The lectures will comprise the general consideration of Insanity in its social and medical aspects, Statistics, Classification, Ætiology, Symptomatology, Diagnosis, Prognosis, Pathology and Treatment. The course will be illustrated by typical cases of the various forms of mental affections. For further particulars apply to Dr. Owen F. McCarthy, Resident Medical Superintendent.

Victoria Hospital (*Incorporated*) (Cork).—There are 75 beds. Clinical instruction on Diseases Peculiar to Children is given. The extern department is open daily at 9.30.

County and City of Cork Lying-in Hospital (Erinville, Western-road; founded 1798).—This hospital contains 22 beds, an Extern Midwifery Department, Gynæcological Department, Extern Department for Women, and Child Welfare Centre. Training Centre for Midwives, preparing for C.M.B. examinations. Fee for six months' attendance, including clinical lectures, £5 5*s*. For further particulars apply to Lucy E. Smith, M.D., secretary to staff.

Cork Maternity (Batchelor's Quay).—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes and there are 8 intern beds. A Child Welfare Centre and Clinic was established in 1919. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate, £5 5*s*. Honorary secretary to staff, Dr. Henry Corby.

Cork Fever Hospital.—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

Cork District Hospital (Douglas-road; 1200 beds).—This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynæcology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. W. E. Ashley Cummins, 17, St. Patrick's-place, honorary secretary, medical staff.

Cork Eye, Ear, and Throat Hospital (Western-road).—This hospital is open to students attending the University College and others. Certificates of attendance for three or six months can be obtained. The hospital contains 35 beds. Over 3000 cases are treated during the year. A course of lectures is delivered during the session; also a post-graduate course of instruction. For further information apply to Dr. Arthur Sandford, Eye, Ear and Throat Hospital.

University College, Galway: School of Medicine.—The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £25 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value £25 each, are reserved for Medical Students. Exhibitions of £10 and £5 are awarded on results of 1st, 2nd, 3rd, and Degree Examinations in Medicine. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Hospital and in the Galway Union and Fever Hospitals, containing on an average 200 patients.

Galway Union and Fever Hospitals (150 beds).—Clinical instruction is given in these hospitals to the Medical Students of University College, Galway. The regulations for Scholarships tenable in the College, and the regulations for degrees and for courses can be obtained from Messrs. O'Gorman and Co., Galway.

Central Hospital, Galway, Prospect Hill Branch (62 beds).—Founded by Act of Parliament.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.), The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance

Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations known as the First, Second, Third, and Fourth Medical Examinations respectively.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject thereof.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory. —In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical Instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum.

Royal Victoria Hospital, Belfast (350 beds).—Students eligible for McGrath, McQuitty, Malcolm, and Coulter Scholarships aggregate annual value £170. Ten House Surgeons and House Physicians. 36 resident pupilships, three months each, annually for Senior Students, of which a proportion is allotted to Women Students. Special Departments for Radiology, Clinical Pathology, V.D., Dermatology, Gynæcology, Vaccine Therapy, Electro-cardiography.

Mater Infirmorum Hospital (220 beds).—Hon. Secretary Medical Staff: Mr. J. B. Moore.

Belfast Infirmary and Hospital (1600 beds).—Clinical courses are given biennially, and course for D.P.H. in Hospital. Intern Venereal Clinic in Infirmary under Corporation scheme. Maternity Hospital recognised for Practical Midwifery training. Particulars may be obtained on application, as to classes, to Dr. McLiesh. Certificate of vaccination class recognised by Local Government Board.

Belfast Hospital for Sick Children, Queen-street.—Clinical instruction is given in this hospital. During the Winter Session two Courses of Lectures are delivered on the Medical and Surgical Diseases incidental to Infancy and Childhood. Demonstrations in Ophthalmology and Pathology are given, and ample opportunities are afforded in the wards (which contain 45 beds), and in the Out-patient Department, which is largely attended, for gaining a practical and theoretical knowledge of the diseases of Infancy and Childhood. This Hospital grants Certificates in Diseases of Children, which are recognised by the various Examining Bodies. A Gold Medal is offered for competition at the close of the session. Fee for the session—2 guineas. For re-attendance—1 guinea. Hon. Secretary to the Medical Staff, Dr. Rowland Hill.

Maternity Hospital, Townsend-street, Belfast.—25 beds in constant occupation, and exclusively devoted to Midwifery and Ante-natal conditions. There is also a large district. Students are welcomed, and clinical lectures are delivered daily by a member of the Staff. There is also a large Ante-Natal Department where clinical instruction is given twice weekly. The Hon. Secretary of the Medical Staff is H. L. Hardy Greer, F.R.C.S.

Ulster Hospital for Children and Women, Templemore-avenue, Belfast (48 beds).—Clinical instruction to students in Diseases of Children, Gynæcology, and Obstetrics. Special departments: Radiology and Eye, Ear, and Throat. Gold Medal awarded annually. One House Surgeon appointed from students of hospital.

Benn Ulster Eye, Ear and Throat Hospital, Incorporated, Clifton-street, Belfast (30 beds).

Belfast Ophthalmic Hospital, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and Laryngology. Clinical instruction is given daily.

Belfast Fever Hospitals.—City Fever Hospital, Purdysburn (330 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-Graduate (D.P.H.) Classes are also held. Lecturer: A. Gardner Robb, M.B., D.P.H.

Belfast Villa Colony Asylum (1000 beds).

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15*s.* to non-Licentiates.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars as to fees and conditions of examination can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence of having before entering on medical studies passed a Preliminary Examination in general education recognised by the Royal Colleges. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of 21 years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.—Every candidate must pass four professional Examinations—at the end of the first, second, third, and fifth years respectively of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; and (2) of having attended a course of—(*a*) lectures on Theoretical Chemistry, six months; (*b*) Practical Chemistry, three months; (*c*) Biology, three months; and (*d*) Physics.

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Biology. The fee for this examination is £15 15*s.*

Second Professional Examination.—Candidates are not admissible to this examination till they have passed in the subjects of the First Professional Examination, and they must produce evidence of having attended (*a*) anatomical dissections, six months; and Lectures on (*b*) Anatomy, six months; (*c*) Physiology, six months; (*d*) Practical Physiology and Histology, three months.

The subjects of the Second Professional Examination are the following:—(1) Anatomy; and (2) Physiology and Histology. The fee for this examination is £10 10*s.*

Third Professional Examination.—Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination, and certificates of having attended courses of instruction in (*a*) the practice of a medico-chirurgical hospital for nine months; (*b*) Pathology—(1) Systematic, (2) Practical, three months each; (*c*) Materia Medica, Pharmacy, and Therapeutics, three months; (*d*) Forensic Medicine and Public Health, three months. The subjects for the Third Professional Examination are the following:—(1) Pathology; (2) Materia Medica, Pharmacy, and Therapeutics; (3) Public Health and Forensic Medicine. The fee for this examination is £9 9*s.* Clinical instruction in Ophthalmic and Aural Surgery, three months. The examination in Ophthalmic and Aural Surgery may be taken immediately after passing the Third Professional Examination.

Final Professional Examination.—Before admission to the Final Examination candidates must have passed the Third Professional Examination and produced evidence of having attended in Division I. the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission in Division II.); the practice of a recognised fever hospital or the fever wards of a recognised clinical hospital, three months; clinical instruction in Mental Diseases, one month (12 attendances); lectures on Medicine, six months at a recognised medical school; of having performed the duties of medical clinical clerk in a recognised hospital for three months; of having attended a course of instruction in post-mortem examinations and demonstrations during one session. In Division II. of having attended the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission to Division I.); lectures on Surgery, six months at a recognised medical school; instruction in Operative Surgery, three months at a recognised medical school; of having performed the duties of surgical dresser in a recognised hospital for three months; of having attended a course of instruction in the practical administration of general anæsthetics. In Division III. of having attended a midwifery hospital or maternity and having been present at 20 labours, six months; instruction on vaccination, six attendances to be certified by a public vaccinator; lectures on midwifery (including diseases peculiar to women and to new-born children), six months at a recognised medical school. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the Divisions I., II., or III., provided he has completed his curriculum as far as concerns the division in which he presents himself. The examination in at least one of the divisions must be deferred till the end of the fifth year.

The subjects of the Final Examination are: (1) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (2) Surgery, Operative; and (3) Midwifery and Gynæcology, Vaccination, and Diseases of New-born Children. The fee is £6 6*s*. Further particulars can be obtained from Alfred Miller, O.B.E., the Secretary of the Committee of Management, Royal College of Surgeons, Stephen's-green, Dublin.

Royal College of Surgeons in Ireland (Schools of Surgery).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5*s*.; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are three professional examinations, the total fees for which amount to £26 5*s*. 6*d*. Women are eligible for the diploma.

There are four examinations—primary, intermediate, Parts I. and II., and final. They are held three times a year, in March, June and December. The primary examination comprises biology, physics, theoretical and practical chemistry (with an examination at the bench). Candidates holding a Pharmaceutical licence are exempt from this subject. Intermediate, Part I., Anatomy and Physiology. Intermediate, Part II., Pathology, Medical Jurisprudence, and Materia Medica and Pharmacy. The intermediate examination comprises anatomy of the whole body (including practical dissections), physiology, practical histology, and materia medica. The final examination comprises medicine, surgery, and midwifery.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 95, Merrion-square, Dublin.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.[1]

Sir Patrick Dun's Hospital, Grand Canal-street, Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Ten Resident Pupils are appointed every four months. Six surgical Dressers and six Clinical Clerks are appointed each month. There are facilities for women students.

Prizes and Medals.—Clinical medals and prizes amounting to about £21 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

Fees.—Winter and summer session, £12 12*s*.; winter session (six months), £8 8*s*.; and summer session (three months), £5 5*s*. Special certificate in anæsthetics, £1 1*s*. The practice of this hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

The Hospital is an official "Treatment Centre" for venereal diseases.

Further information will be supplied by the Hon. Secretary to the Medical Board.

Coombe Lying-in Hospital and Guinness Dispensary for the Treatment of Diseases Peculiar to Women, Dublin.—This hospital contains 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. There is accommodation for intern pupils who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. The residents' quarters are comfortable. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Fees: Extern pupils for full course of six months, £8 8*s.*; three months, £4 4*s.* Intern pupils, one month, £4 4*s.*; each consecutive month, £3 3*s.*; six months, £18 18*s.* Registration fee, in advance, 10*s.* 6*d.* Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the Hospital.

---

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in some of the Irish centres have been described.

ADELAIDE HOSPITAL, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s.*; six months, £8 8*s.* Summer, three months, £5 5*s.*[1] Two resident surgeons are elected half-yearly and four or more resident pupils every four months. At the termination of the session prizes in Clinical Medicine, in Surgery, in Gynæcology, and in Dermatology will be awarded.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Dr. H. Bewley.

JERVIS-STREET HOSPITAL, Dublin.—Founded 1718; rebuilt 1886. 130 beds. A new out-patient department has been completed and contains all modern requirements.

MATER MISERICORDIÆ HOSPITAL, Dublin. (Under the care of the Sisters of Mercy.)—This Hospital was founded in 1861 by the Sisters of Mercy. It is the largest in Ireland, containing 382 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical operations will be performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Three House Physicians, nine House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed. and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases; also a Training School and a Home for Trained Nurses in connexion with the Hospital. Trained and experienced Nurses who have passed a qualifying examination in nursing can be obtained on application to the Lady Superior, Mater Misericordiæ Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. John O'Donnell, 3, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Medical Board, Mr. H. Barniville, 9, Merrion-square.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY. This hospital was founded in 1753 and now contains 166 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical Clinical Clerks and Surgical Resident Pupils and Dressers are appointed every three months, and House Surgeons and Clinical Assistants are elected annually. Apply to Hon. Treasurer of Medical Board.

MERCER'S HOSPITAL.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients. An electrocardiograph has been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from amongst the most deserving members of the class.

Fees.—Winter, six months, £8 8*s.*; Summer, three months, £5 5*s.*; nine months, £12 12*s.*

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square, Dublin.

NATIONAL MATERNITY HOSPITAL, Holles-street, Dublin.—Established 1894. The hospital consists of an Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children. About 1035 cases are admitted and over 300 operations are performed annually. Every facility is given for the carrying out of practical work. Post-graduate and special courses are arranged for at any time. Certicates of attendance at this hospital are recognised by all the licensing bodies. Terms (three months' course) 6 guineas. Board £2 2*s.* per week. Medical men can take out Post-graduate courses by paying a fee of £3 3*s.* for the month. Clinical Lectures are given daily and Oral Lectures four times per week. During the past year over 50 Post-graduate students were admitted. The L.M. Diploma is given by special examination on arrangement with the Masters. Further particulars can be obtained from the Masters: Sir Andrew Horne, 94, Merrion-square, Dublin; Dr. Patrick McArdle, 27, Merrion-square; or from the Secretary, Holles-street, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS (HOUSE OF INDUSTRY HOSPITALS), Dublin.—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 20 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon. Secretary, 69, Fitzwilliam-square, Dublin.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually and 500 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M. and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s*., months other than the first £4 4*s*., three months £12 12*s*., six months £21. For further particulars apply to the Master.

---

[1] Special Lectures in Dermatology are given weekly; also practical demonstrations on the treatment of fractures from time to time.

ROYAL CITY OF DUBLIN HOSPITAL.—Founded 1832; enlarged 1851; rebuilt 1893. 130 beds. There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. Secretary: G. R. Shine.

ROYAL VICTORIA EYE AND EAR HOSPITAL, Dublin.—Established 1844. Incorporated 1897. 102 beds. In-patients, 1499; out-patients, 8492. Two house surgeons for Eye and one for Ear appointed annually.

DR. STEEVENS' HOSPITAL, Dublin (Kingsbridge).—Established 1720. 250 beds. Patients, intern, 1329; extern dispensary attendances, including special V.D. Clinic, 16,390. There is accommodation for 12 Resident Pupils, each of whom is provided with a separate bedroom, and board is supplied by the Hospital, at a reasonable rate. All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

ST. VINCENT'S HOSPITAL AND DISPENSARY, Dublin.—Established 1834. 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for Senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Farrell gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the Surgeon McArdle Prize, value £20. In the coming term it is hoped that there will be opened a New Extern Department and a New Pathological Laboratory. Dr. Meenan, hon. secretary, 28, Fitzwilliam-square.

DIPLOMAS IN PSYCHOLOGICAL MEDICINE.

THE Universities of Cambridge, London, Durham, Leeds, Manchester, and Edinburgh, and the Conjoint Board of the R.C.P. Lond. and R.C.S. Eng. now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies. Much thought to-day is being directed to the medical side of lunacy administration. There is a strong feeling within the medical profession, as well as among the public, that the numerous barriers preventing the intelligent treatment of in-patient mental cases should be relaxed. The position of uncertifiable cases requiring mental treatment is being considered, for many of these cases pass from uncertifiable into certifiable, by which time they have become resistant to treatment. There is no doubt whatever of the high scientific standard of the work that is to-day projected by all leading psychiatrists, and as the conditions of service improve there should be no lack of recruits of the right stamp.

In London, courses of instruction for the Diploma in Psychological Medicine are given at the Maudsley Hospital, Denmark Hill. The course consists of two parts, and is adapted for the diploma of the Conjoint Board, the University of London, or the University of Cambridge, Part I. being conducted by Sir Frederick Mott, Dr. F. Golla, and Dr. Henry Devine. Sir Frederick Mott gives eight lectures on the anatomy of the nervous system, followed by practical instruction and demonstrations on the methods of staining nervous tissue and preparing it for microscopical examination; microscopic sections are distributed, illustrating the principal diseases of the nervous system, for mounting as a permanent collection. Dr. Golla gives eight lectures on the physiology of the nervous system, followed by practical instruction and demonstrations on physiological chemistry (including the chemistry of the nervous system, physico-chemical methods, blood and urine analysis, and gastric contents analysis), and practical physiology (including the recording of reflexes and tremors in man and the action of drugs on the autonomic system). Similarly, Dr. Devine gives eight lectures on psychology, followed by practical instruction and demonstration of psycho-physical methods, and memory and intelligence tests.

In Part II. of the course Sir Frederick Mott gives six lectures on the pathology of mental diseases, including brain syphilis, its symptomatology and treatment. Dr. Bernard Hart gives eight lectures on the psychoneuroses. Sir Frederick Mott and Dr. Golla give 12 clinical demonstrations in neurology, the first six demonstrations being given by Dr. Golla at the Hospital for Paralysis and Epilepsy, Maida Vale. Dr. F. C. Shrubsall gives eight lectures on the practical aspect of mental deficiency. Dr. W. C. Sullivan, medical superintendent of Broadmoor Asylum, gives six lectures on crime and insanity. Dr. C. Hubert Bond and Dr. E. Mapother give a course of lectures on the differential diagnosis and treatment of mental disorders and the legal relationships of insanity. The fee for the whole course (Parts I. and II.) is 15 guineas, or for either part separately 10 guineas; for one single series of lectures in Part I. the fee is four guineas, and in Part II. two guineas. Inquiries as to lectures, &c., should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5.

Part II. of the course will commence during the first week of October.

A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various Universities, is held at Bethlem Royal Hospital twice annually, during the spring and autumn. The next course, which begins on Sept. 17th, will consist of two parts, A and B. Part A deals with anatomy, histology and physiology of the nervous system, and psychology, the lecturers being Drs. S. A. K. Wilson, C. Worster-Drought, F. C. E. Danvers-Atkinson, Clement Lovell, William Brown, and J. A. Hadfield, and demonstrations of the normal anatomy and histology of the central nervous system and endocrine glands will be given. Part B includes Neurology, Psychological Medicine, and Mental Deficiency, the additional lecturers being Drs. James Collier, R. H. Cole, E. D. Macnamara, J. G. Porter Phillips, Thomas Beaton, C. Stanford Read, W. H. B. Stoddart, M. Hamblin Smith, and A. F. Tredgold. The fee for the full course is 15 guineas; for Part A separately 10 guineas, and for Part B separately 10 guineas.

All communications concerning the course should be addressed to the Physician-Superintendent, Bethlem Royal Hospital, London, S.E. 1.

In addition clinical instruction in psychological medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 A.M. The fee for post-graduates is five guineas for three months' attendance, but a reduction is made to those who attend the course for the Diploma in Psychological Medicine.

WE take this opportunity of thanking the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

THE LANCET.

LONDON: SATURDAY, AUGUST 25, 1923.

THE OUTLOOK IN MEDICINE.

THE prospect in medicine for the newly qualified man or woman has in these days become very wide, and we set out in the present issue signposts to a number of different careers which may be chosen. The choice is largely a matter of personal bent, for in no single direction is there any doubt that average ability combined with diligence and good health will produce an economic return. But the zest associated with any particular career will depend more than anything else upon the practitioner's relation to his environment. The true spirit of medicine is the love of humanity associated with the love of craft, and the free and unfettered practice of his craft has been profoundly modified by the happenings of the last 20 years. The relation between the State and the doctor is changing; apart from the fact that he may be called upon to undertake official duties in the public service, the doctor is liable under statute in the following respects[1]:—

1. He must certify births and deaths (Births and Deaths Registration Act, 1874), and notify all births within 36 hours (Notification of Births Acts, 1907–15); he must notify cases of infectious disease (Infectious Diseases Notification Acts, 1889 and 1899, and special notification regulations as issued), of industrial poisoning (Factory and Workshop Act, 1901), and of verminous children (Children Act, 1908). He must also be ready to vaccinate (Vaccination Acts, 1871–1907) and to certify the removal of infectious cases to hospital (Public Health Act, 1875).
2. He may be called upon to inspect and certify for house disinfection (Public Health Act, 1875, and Infectious Disease Prevention Act, 1890), and be prepared to issue certificates for the removal and burial of dead bodies (Ibid.).
3. He may be required to inspect and condemn in regard to nuisances and insanitary house property (Public Health Act, 1875, or Amendment Act, 1907), or inquire into unhealthy or insanitary areas (Housing of the Working Classes Act, 1890).
4. He must know something of the ill-effect upon health of dangerous or offensive trades (Public Health Act, 1875), and of unsound food (Public Health (Unsound Food) Regulations, 1908).
5. He must be competent to diagnose all forms of mental disease (Mental Deficiency Act, 1913).
6. He must be available to respond to the requirements of the local sanitary authority for the provision of medical assistance and treatment for the poorer inhabitants of the district in which he lives (Public Health Act, 1875, s. 133).
7. He is liable for a series of duties in regard to workmen's compensation (Workmen's Compensation Act, 1906, s. 8), superannuation, and pension claims (Ministry of Pensions Act).
8. He may be called in by a midwife to assist in cases of emergency (Midwives Act, 1918, s. 25).
9. The local education authority may avail themselves of his services in connexion with the treatment of children and young persons (Education Act, 1918, s. 25).

Besides these obligations which no practitioner can escape there are others which he can voluntarily take upon himself. Systematic provision has been initiated for tuberculosis, venereal disease, and maternity and infant welfare; the organised treatment of early mental affection, of orthopædic cases, and of industrial diseases is under discussion, while the National Insurance Act of 1911 brought at one stroke 12 million insured persons into medical benefit, to be provided under contract by some 12,000 doctors. The Act imposes obligations and privileges on both sides which can hardly be enforced without continuous supervision, and this is distasteful[2] to a body of competent and qualified medical men. Their voluntary exclusion from this service does not imply "its irremediable failure," but those who feel with the non-panel advocate will not find congenial occupation within the boundaries of the Act, and should not try to do so. Submission to various kinds of interference is a condition of many of the careers enumerated. The régime of the medical departments of the three fighting services and of the Indian Medical Service, not as strict as it was, is still precise, and in any branch of the Public Health Service the doctor acts under the instruction of his official superior, who is finally responsible to the Public Health Committee of the area, a body which may consist wholly of laymen, and from which even the medical officer of health has no right of direct appeal to the council of which he is the servant.

But the immunity of the individual practitioner from interference is largely illusory. Individualism in the past, desirable as it was in many respects, resulted in the sweating and exploitation of practitioners by friendly societies and clubs, while any form of collective bargaining does away to some extent with the liberty of the individual bargainer. The feeling of individual security received a rude shock two years ago when an action was brought against an independent practitioner for alleged negligence in the treatment of a fractured femur. Though evidence was brought forward to show that the case was treated on approved modern methods, the jury returned a verdict against him with damages to the amount of £750, the total costs of the action amounting to £2250. The practitioner, being unprotected by membership of any defence society, would have himself incurred this great loss, had not the medical profession as a whole come to his aid and voluntarily contributed a sum of over £1730. Able himself to smile at bad fortune, "for," as he wrote, "the Fates singled him out to try his courage," the obvious lesson of his misfortune has not been lost, for the present membership of the two English medical defence societies exceeds 17,500 and is increasing at the rate of 100 or more a month. One of these societies has now raised to £3000 the amount of damage against which the practitioner can insure, and there is also a Scottish protection society. In the coroner's court, too, the individual practitioner must count on appearing more frequently and on receiving at times much greater attention in the lay press. No doubt, in all these matters the right course for the practitioner is "to preserve such a character that if accused the presumption will be in his favour."[3] Nevertheless, he needs to be well versed in the laws of evidence and should add to his rôle of well-informed and truthful witness some ophidian readiness in repelling hostile attack. For the conduct of practice itself the Golden Rule and the desire to do his best for his patient will suffice; the less said about these obvious professional virtues the better, but we doubt whether the abortive discussion of three years ago at the General Medical Council on the teaching of medical ethics should not be revived now that other urgent educational matters have been dealt with. Room in the curriculum might be found for instruction in the responsibilities of the medical man towards the State, and it is reasonable for the students to receive during pupillage information upon the working of the Medical Acts and upon all rules and regulations which will form the conditions of any State service undertaken later.

NAVAL MEDICAL SERVICE.

The life offered to officers of the Royal Naval Medical Service is one that ought to appeal to a large section of recently qualified medical men. There is no intention in what follows, under this or the subsequent headings, to pit one Service against the other or to recruit in one direction more than in another. The particular regulations for each Service should suffice to give each man the necessary impetus for a decision, but it is useless to disguise the fact that the attitude of the authorities in respect to the compulsory retirement at the age of 50 of a group of surgeon commanders who were under contract to be employed until the age of 55 has produced an unfortunate impression. It creates a difficulty for those who are in a position to advise young men as to their future careers when they give counsel based upon engagements which may later be repudiated. The situation has evoked a formal protest from the British Medical Association, and although no specific action was recommended to the Association by its Representative Body, certain protests have found their way into the public press and cannot have failed to prejudice recruiting for the service.

In the Navy the young medical officer sees the world in congenial company and with an assured position, the pay is good, the pensions are commensurate, and the opportunities offered now for scientific work are real, while, if they are taken, promotion awaits the officer on grounds of professional merit.

Rank of Surgeon Lieutenant-Commander will be granted to surgeons at the expiration of six years from date of entry, and the point upon which stress should be laid is that special promotion can be made in cases of conspicuous professional merit, which is thus placed on a par with general service. Six years later the period of promotion to Surgeon Commander is reached, after having passed the qualifying examination, when again special promotions can be made for conspicuous professional merit as well as for distinguished service; but promotions are limited in number, save, of course, for gallantry in action. This recognition of professional attainment should prove a very real incentive to progressive scientific work. The same principle prevails in the higher ranks. Promotions to Surgeon Captain and later to Surgeon Rear-Admiral are made strictly by selection, but are confined to officers who prove fitted, both professionally and as administrators, for this rank.

Naval life may lead to opportunities for putting into practice much of what has been learned in the clinical wards of a hospital. Further, the opening for preventive medicine is large and many-sided, while appointments to the large shore establishments enable medical officers to keep their work modern.

New chemical explosives, as well as the extraordinary behaviour of common articles under extraordinary conditions of stowage, furnish perpetual problems and surprises for the medical officer on board ship, and bring him into intimate connexion with his charges in a way that is particularly necessary considering the conditions of life. No medical officer can expect to succeed unless he secures the confidence of those committed to his charge, and the health lectures which he is bound to deliver will be much more fruitful if they are delivered to an audience which trusts him. Moreover, the delivery of official lectures does not end this side of the medical officer's duties. He must be ready to answer questions, sometimes of real acuteness, which are put to him by the modern blue-jacket, and he will find that his lectures will often afford a starting point of work that may develop into great professional interest. Thus, without his being necessarily a psychologist, his influence will be felt by both officers and men, until the well-being of the ship may be profoundly affected by the extent of his tact and skill; for example, small matters assume undue proportion under stress of confinement, and the medical officer should be quick to detect danger signs and warn his commanding officer. Numerous changes have been introduced during the last 20 years into the naval dietary, many of which were the outcome of representations and research by naval medical officers. The work wants carrying on, for much of it has gone to show that the food problem is very complicated. Every medical officer on board ship should make himself acquainted with food values and the human powers of assimilation under varying conditions of work and climate, and here there is ample scope for research. The modern requirements of gunnery and navigation necessitate precision in their use and have made ophthalmology a valuable subject for study in the Navy. The physical training of both officers and men is based on physiological axioms which are peculiarly the field of the medical officer; this training should be the subject of a watchful eye. There is no lack of scope here for professional work without making any reference to the vast problems which have to be faced when the medical officer has to arrange his particular department to the best advantage during or after an action. It is certain that he will not be able to do this unless in times of peace he gets himself ready by study. Lastly, there is the whole field of venereal and tropical disease.

The young medical officer need not be afraid that his work will be without scientific interest if he takes the opportunities offered him.

Conditions of Service.

For the time being the regulations for entry by examination into the permanent service are in abeyance, but a short service scheme providing for transfer to the permanent service has been inaugurated. The regulations for the entry of surgeon lieutenants under this scheme provide for the usual qualifications of registration, good character, physical fitness, and age—the age not to exceed 30 years. The conditions of service are a three years' engagement with an option of a further year, to serve when and where required under the general rules of the service as regards discipline, and to rank with, but after, surgeon lieutenants in the permanent service, and to receive two calendar months' notice of services being no longer required.

The pay is £1 6*s.* 6*d.* per day, or £483 12*s.* 6*d.* per year, while there is a gratuity on discharge of £8 6*s.* 8*d.* for each completed month of service. A gratuity to officers invalided for causes not within their own control is payable, while the same allowances are received as are payable to permanent officers of similar rank, and lodging and provision allowances will be made and be subjected to revision from time to time. The rates mentioned are £80 a year when employed on shore without quarters, and £60 a year in lieu of rations when not victualled in kind, while arrangements are made for officers in temporary employment on shore. No unemployed or half pay is granted, but there are pensions for wounds or injury on duty, and in the event of death the officer's widow and children would fall under regulations applying to officers on the permanent list. There is an equipment allowance for ordinary uniform of £50, but the officer provides himself with a pocket case of instruments and a stethoscope.

A short service surgeon lieutenant after six months' service, on application to the Secretary of the Admiralty, may be considered for transfer to the permanent service on a satisfactory report being received from the senior medical officer of the Squadron, Hospital or Depot in which he has served or is serving as to his professional ability, and a favourable report from his commanding officer as to conduct. Such candidates must have been under the age of 28 on joining for short service, and officers so transferred will not be eligible for the gratuities provided. They will be permitted to count their seniority from date of entry for short service for purposes of promotion and for increment of full pay, and similarly they will be permitted to count their service from the date of entry for purposes of retired pay, but for purposes of retiring gratuity on the permanent officers' scale their services will be reckoned only from the date of transfer to the permanent list, this date being that of receipt in the ship or establishment in which the officer is serving of the order for his transfer to the permanent list. Until that date he will retain his temporary rate of pay.

If a short-service lieutenant wishes to transfer to the permanent service he will then come under the following conditions of pay and pensions :—

RATES OF PAY AND PENSION.

——	Year of 365 days.			One day.		
	£	s.	d.	£	s.	d.
Surgeon Rear-Admiral ..	1916	5	0	5	5	0
Surgeon Captain :						
On promotion	1186	5	0	3	5	0
After 3 years' seniority ..	1277	10	0	3	10	0
,, 6 ,, ..	1368	15	0	3	15	0
,, 9 ,, ..	1460	0	0	4	0	0
Surgeon Commander :						
On promotion	821	5	0	2	5	0
After 3 years' seniority	894	5	0	2	9	0
,, 6 ,, ..	967	5	0	2	13	0
,, 9 ,, ..	1040	5	0	2	17	0
Surgeon Lieutenant - Commander :						
On promotion	638	15	0	1	15	0
After 3 years' seniority	675	5	0	1	17	0
Surgeon Lieutenant :						
On entry	438	0	0	1	4	0
After 3 years' seniority ..	529	5	0	1	9	0

On first appointment to the Service, Medical Officers will receive full pay from date of appointment, but subject to the provisions of Article 1347 of the King's Regulations, 1913.

Flag Allowances.

An allowance of 5*s.* 0*d.* a day in addition to full pay is granted to the Senior Medical Officer of a flagship bearing the flag of a Commander-in-Chief. An allowance of 2*s.* 6*d.* a day is granted to the Senior Medical Officer of a ship bearing other flags or broad pendants.

Rates of Pension.

Compulsory retirement will be as follows :—

(i) Surgeon Rear-Admirals retire at the age of 60 with retired pay at the rate of £900 per annum plus £22 per annum for each year's service over 27 years counting for retired pay, subject to a maximum rate of £1010 per annum. If, however, less than 27 years' service counting towards retired pay is rendered, a deduction of £22 per annum is made for each full year wanting to complete that period, subject to a minimum of £790 per annum.

(ii) Surgeon Captains retire at the age of 55. Maximum retired pay, £900.

(iii) Surgeon Commanders retire at the age of 50. Maximum retired pay, £600.

(iv) Surgeon Lieutenant-Commanders and Lieutenants retire at the age of 45. Maximum retired pay, £450.

Subject to these maxima, the rates of retired pay for Surgeon Captains, Surgeon Commanders, Surgeon Lieutenant-Commanders, and Surgeon Lieutenants are as follows :—

Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)		Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)	
			Addition.	Deduction.				Addition.	Deduction.
	£ (p.a.)		£ (p.a.)	£ (p.a.)		£ (p.a.)		£ (p.a.)	£ (p.a.)
55	790	24	22	15	47	562	20	15	15
54	765	24	22	15	46	525	20	15	15
53	742	23	22	15	45	487	19	15	15
52	720	23	22	15	44	450	19	15	15
51	697	22	22	15	43	412	18	15	15
50	675	22	15	15	42	375	18	15	15
49	637	21	15	15	41	337	17	15	15
48	600	21	15	15	40	300	17	15	15

(p.a.) = per annum.

(A) Addition for each full year's service in excess of that specified in column 3 or deduction for each full year wanting to complete that period of service—addition or deduction limited to five years in each case.

DENTAL BRANCH.

The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of Surgeon Commander (D) is not open to them. They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work, and there is every opportunity for them to maintain a high standard of professional skill.

Entry is by competition, the Competitive Entrance Examination being similar in scope to the Final Qualifying Examination. Candidates are required to produce the usual certificates of birth, registration and of character, and must be physically fit for service anywhere. They must not be more than 28 years of age on the day of commencement of the entrance examination. An outfit allowance of £50 is payable to officers finally entered.

Provision has been made for candidates who, at the time of passing the examination, hold or are about to hold an appointment as Dental Officer in a recognised Civil Hospital. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list. It is also proposed to allow a three months' Post-graduate Course to Surgeon Lieutenant Commanders (D) of over two years' seniority. The rates of full pay are as follows :—

Pay and Allowances.

NOTE.—20 per cent. of these rates of full pay, half-pay, and retired pay are considered as due to the present high cost of living, and are subject to change on or after the 1st July 1924, and thereafter every three years, either upwards or downwards, according as the cost of living rises or falls.

Full Pay.

——	Year of 365 Days.			One Day.		
Surgeon Lieutenant (D) :	£	s.	d.	£	s.	d.
On entry	401	10	0	1	2	0
After three years	492	15	0	1	7	0
Surgeon Lieutenant-Commander (D) :						
On promotion	593	2	6	1	12	6
After 3 years' seniority	629	12	6	1	14	6
,, 6 ,, ,, ...	666	2	6	1	16	6
,, 9 ,, ,, ...	730	0	0	2	0	0
Surgeon Commander (D) :						
On promotion	775	12	6	2	2	6
After 3 years' seniority	839	10	0	2	6	0
,, 6 ,, ,, ...	912	10	0	2	10	0

On first appointment to the Service, Dental Officers will receive full pay from the date of appointment, but subject to the provisions of Article 1347 of the King's Regulations, 1913.

Dental Officers are eligible for the same rates of lodging and provision allowances as other officers of equivalent rank and are entitled to the same privileges. The rates of half-pay are :—

Half-Pay.—In the case of Dental Officers, a distinction is to be drawn between (*a*) Officers awaiting employment, and (*b*) those who are permitted, for private reasons, which the Admiralty regard as satisfactory, to refuse an appointment or to have their appointment cancelled, or who are unemployed at own request or in consequence of misconduct.

In the former case, (*a*), Officers are to receive unemployed pay, as follows :—

For the first six calendar months, full pay of rank (without allowances). For the next six calendar months :—

	s.	d.	
Surgeon Lieutenants (D)	17	0	a day
,, Lieutenant-Commanders (D) ..	22	6	,,
,, Commanders (D)	27	6	,,

Thereafter :—Half the full pay of their rank and seniority on the Executive Officers' scale, viz. :—

	s.	d.	
Surgeon Lieutenants (D)	8	6	a day
,, ,, of 4 years' seniority ..	10	0	,,
,, Lieutenant-Commanders (D)	15	0	,,
,, ,, ,, of 3 years' seniority	16	0	,,
Surgeon Lieutenant-Commanders (D) of 6 years' seniority	17	0	,,
Surgeon Commanders (D)	20	0	,,
,, ,, of 3 years' seniority	22	0	,,
,, ,, of 6 ,, ,,	24	0	,,

Unemployed pay will not, however, be granted in cases, where an Officer is undertaking continuous professional work for which payment is made.

In the latter case, (*b*), Officers may receive half the full pay of their rank and seniority on the Executive Officers' scale.

Periods during which unemployed Full Pay or Unemployed Pay are received will only count as half-pay time.

An Officer who is permitted, for private reasons, to decline an appointment, or to have his appointment cancelled will not be entitled to any Unemployed Pay. In such cases, Officers may be placed on Half-Pay, and the conditions of retirement, Widows' Pensions, Leave, &c., are the same as for medical officers of equivalent rank and seniority.

Arrangements are also made whereby officers may be allowed to withdraw from the Service after four years' service and receive gratuities on the following scale :—

(*a*) Gratuities will be awarded on retirement and withdrawal on the undermentioned scale.

Rank.		Gratuity.		
		£	*s.*	*d.*
Surgeon Lieutenant (D), Surgeon Lieutenant-Commander (D), and Surgeon Commander (D) :				
After 4 years' full-pay service		500	0	0
,, 8 ,, ,,	including service allowed by paragraph 13.	1,000	0	0
,, 12 ,, ,,		1,500	0	0
,, 16 ,, ,,		2,250	0	0

ARMY MEDICAL SERVICE.

The recent alterations in the conditions of service in the Royal Army Medical Corps, which constituted, as we said at the time, the greatest reform that has taken place in that Service for a generation, have well fulfilled their promise. For many reasons which are obvious and have been detailed on previous occasions, the Service can be thoroughly recommended to young medical practitioners. Competitive examinations for commissions into the R.A.M.C. are held twice a year, usually in January and July. The Regulations for admission to the R.A.M.C. should be obtained from the Army Medical Department, War Office, London, S.W. 1, and carefully studied.

These are the things which the man who contemplates joining the Service should bear in mind. The rates of pay and allowances are good; the chances of seeing the world and the opportunities for post-graduate study are generous, and the work is nowadays varied, responsible, and interesting. At certain periods the young officer is relieved from all other duties for five months for the purpose of post-graduate study. During this period he is on full pay and the fees for his courses of instruction are paid by the State. His time is devoted to post-graduate work, and the leading clinical and scientific institutions are coöperating to secure that this post-graduate work shall be real and fruitful. Officers who show a marked aptitude for special subjects and have had previous practical experience in them are now selected to undergo a specialist course lasting for a further four months, thus giving these officers a post-graduate course of nine months. At the same time, in districts where the privilege would be of the most practical value, opportunities are forthcoming for young officers to attend the clinical practice of large local general hospitals.

By a Royal Warrant issued in September, 1919, medical and combatant officers were placed on the same footing as regards retired pay, and the fact that medical officers enter the Service after a long and expensive training some five years later in life than combatant officers was overlooked. This inequality of treatment has now been rectified, with the result that a medical officer of 20 years' service or over gets £75 per annum more pension than a combatant officer with the same number of years' service.

Once again let us deal with the most frequently repeated criticism of the Service—namely, that administration eternally takes the *pas* of science. The Directorates in Pathology and Hygiene which were recently created in the R.A.M.C., and which we may say have proved a marked success, form a complete answer to such criticism, however just it was in the past. This scheme of creating Directorates permits specially selected men to rise from all ranks to Major-General on the strength of their scientific work. Hitherto, a few notable men being excepted, the rule in the R.A.M.C. has been that, whatever a man's qualifications or abilities, on attaining the rank of Lieutenant-Colonel, he must be prepared to go off into administrative work and leave his scientific duties to his juniors. If he preferred to remain working in bacteriology, in preventive medicine and hygiene, or in tropical diseases, for example, he could do so, but, except in extraordinarily fortunate circumstances for himself, he would find that his devotion to science had cost him all chances of further rise in his Service, promotion being reserved for the administrative billets. This now has all been changed, and the change has its expression in these Directorates. All ranks up to and including the rank of Lieutenant-Colonel can draw specialist pay and hold appointments carrying allowances. The following is the scale of additional pay and charge pay :—

Additional Pay and Charge Pay for Officers of the R.A.M.C.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under, within a limit of 5*s.* a day :—

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology, including Venereal Disease, 5*s.* daily.

Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 2*s.* 6*d.* daily.

Officers granted temporary higher rank while holding appointments in the services of hygiene and pathology will not be eligible for additional pay as specialists while holding such temporary rank.

(2) (*a*) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds	.. 2*s.* 6*d.* daily.	300 beds	.. 7*s.* 6*d.* daily.
150 ,,	.. 5*s.* 0*d.* ,,	500 ,,	.. 10*s.* 0*d.* ,,

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates.

	Daily.	
	s.	d.
(*b*) Senior medical officer, Royal Arsenal not exceeding	10	0
(*c*) Officer in command of the depot, Royal Army Medical Corps	5	0
(*d*) The senior officer of Our Army Medical Service with an army in the field : A rate to be fixed by Our Army Council according to the magnitude of the charge.		
(*e*) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5	0
(*f*) Adjutant R.A.M.C. Depôt	5	0
(*g*) Adjutant R.A.M.C. (Territorial Army)	2	6

Further, an officer, graded as a specialist, and appointed to the charge of a medical or surgical division of a general hospital may be allowed to retain his additional pay and to draw the rate of charge pay laid down for the officer in charge of a medical or surgical division of a general hospital, provided that the total of additional and charge pay so drawn does not exceed the rate of charge pay drawn by the officer in charge of the hospital. With this exception charge pay and additional pay as specialist will not be issuable concurrently. It may be here pointed out that the distinction between scientific and administrative work is largely verbal. Take the conduct of a large hospital—is it possible to separate the scientific routine which is designed to ensure progressive therapeutics from the administrative work which provides and maintains the premises and service, and selects and oversees the personnel ?

Under the conditions enumerated the possibilities or good workers is very great in the R.A.M.C.; they will attain to positions of proper trust and emolument y scientific work. This should much improve ecruiting among the officers of the R.A.M.C. But here will almost certainly follow arrangements by which all special medical service will receive higher onsideration in the Corps. Not only is there in he work of the Army Medical Department scope for riginal labour and research in tropical disease, n preventive medicine, and in bacteriology, as well s in the vast clinical field open to the specialist n medicine, surgery, or gynæcology, in venereal lisease, in ophthalmology, and so on, but it is proposed o develop a scheme whereby child welfare shall be ndertaken systematically by the R.A.M.C. A cheme of this sort is already running successfully at ldershot, and we see in this direction a fine opening or preventive medicine, and one which should bring he officers of the R.A.M.C. into touch with the soldiers n a valuable and intimate manner.

The above schemes for the stimulation of purely rofessional work among officers of the Corps must ot be taken to imply that instruction in adminis- rative work has been overlooked. One of the essons of the war was that good administration must xist for the fullest benefit to be obtained from he professional talent available. The necessity of raining officers who may display capacity for rganisation and administration has not been lost ight of, and there are many appointments of varying legrees of importance and responsibility open to fficers who desire to take up this side of the Corps' luties. The inclusion of Officers of the Corps among hose officers who are now detailed to undergo courses t the School of Army Administration, Chisledon, is a tep of great importance in this connexion.

RATES OF PAY AND PENSION.

The following table shows the

Total Emoluments: Royal Army Medical Corps.

Appointment.	Pay.	Rations.	Servant.	Married and *Unmarried.** Lodging.	Fuel and light (average).	Furniture allowance.	Total (per annum).

* Rates for unmarried officers in italics.

The allowance rates vary slightly from time to time. harge pay (2*s.* 6*d.*–10*s.* per day) and specialist's pay (2*s.* 6*d.*– *s.* per day)—i.e., from £45–£180 per annum—in addition for considerable percentage of officers.

Retirement and Retired Pay.

The following are the rates of pension and retired ay :—

1. Retired pay will consist of two parts: (*a*) a service ement based on the officer's total service; (*b*) a rank ement for the rank from which the officer retires. An fficer with less than 20 complete years' service will not be igible for retired pay.

2. The scale will be as follows :—

(*a*) Service element.—£15 a year for each completed year of service.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant - Colonel	150	30	240
Colonel	290	50	390
Major-General ..	440	50	540
Lieutenant - General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together :—

	£		£
Captain and Subaltern ..	300	Colonel	800
Major	450	Major-General ..	1000
Lieutenant-Colonel ..	600	Lieutenant-General	1200

Officers with 8½ and less than 20 years' service may be permitted to retire with a gratuity varying from £1000 to £2500.

Arrangements have been made for the appointment of Consultants in both Medicine and Surgery and the ranks of Colonel and Major-General will now be open to such Officers. The duties of these Officers are to visit all Commands and advise the Director-General, as the result of their inspections on the spot, with regard to the professional work being carried on in the hospitals, and the degree of efficiency attained by the personnel with whom they are respectively concerned. This should ensure a high standard of performance if only because of the satisfactory feeling that good work will not by accident remain unnoticed.

The present holders of these posts are Consultant in Surgery, Maj.-Gen. E. M. Pilcher, late Professor of Surgery at the Royal Army Medical College; Consultant in Medicine, Colonel J. C. Kennedy, late Professor of Tropical Medicine at the Royal Army Medical College.

THE ARMY DENTAL CORPS.

The Corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force and personnel is required to serve under either force and be interchangeable. Officers and other ranks posted for duty with the Royal Air Force will perform their duties under the Regulations of the Royal Air Force for the employment of dental personnel, but the conditions in the following tables apply equally in either force. Promotion is carried out on one general list. The regulations for admission to the Army Dental Corps should be obtained from the Secretary, War Office, and carefully studied.

OFFICERS: *Appointment and Promotion.*

1. Commissions as lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

2. An officer shall be eligible for promotion to the rank of captain on completion of three and a half years' service in the Corps provided he has previously qualified in such manner as may be prescribed by the Army Council.

3. Promotion to the rank of major and lieutenant-colonel to fill the establishments laid down from time to time for those ranks, shall be made by selection of the Army Council, provided the officer has previously qualified for promotion to those ranks in such manner [illegible] may be prescribed by the Army Council.

4. Certain appointments in the rank of lieutenant-colonel and major have been approved to fill the establishment. The remainder of the appointments are in the rank of lieutenant, except in cases where service of three and a half years or more has been given as a temporary dental officer when the rank of captain will be given. Service as a temporary dental officer will count towards the three and a half years for promotion to captain.

Pay.

The following are the rates for officers of the Army Dental Corps :—

	Per diem.		
	£	s.	d.
Lieutenant	1	0	
Captain	1	5	0
Captain, after 6 years' total service	1	6	6
Captain, ,, 10 ,, ,,	1	8	6
Major	1	13	0
Major, after 15 years' total service	1	18	0
Lieut.-Colonel	2	7	6
Lieut.-Colonel, after 20 years' total service	2	10	0
Lieut.-Colonel, ,, 25 ,, ,,	2	12	6

Allowances.

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the R.A.M.C.

Retirement and Retired Pay or Gratuity.

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' service.

(3) Earlier retirement on gratuity may be allowed :—

After 8½ years' service in the Corps, gratuity of	£1000.
,, 15 ,, ,, ,,	£1800.
,, 18 ,, ,, ,,	£2500.

(4) Retirement will be compulsory at the age of 55 years.

(5) A lieutenant who does not qualify for promotion within three and a half years' service in the Corps will be retired ; and a captain who fails to qualify for promotion to major within twelve years' service in the Corps will be retired on any gratuity for which he may be eligible under paragraph 3.

Other Ranks.

The rates of pay of warrant officers, non-commisioned officers and men are those provided in the Warrant of Sept. 13th, 1919, *vide* Army Order 324 of 1919.

The aim of the Corps is the prevention of wastage of man power on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier will be re-inspected at least once a year and his dental efficiency maintained at the best standard possible. As recruits are not now enlisted unless they have sufficient natural teeth to enable them to masticate efficiently it is hoped that the conservative nature of the treatment they will receive will reduce considerably the percentage of artificial dentures required.

The "other ranks" of the Corps consist of dental mechanics and clerk orderlies. Training of dental mechanics has been proceeding for some time at the Central Dental Laboratory, Aldershot, and it is not proposed to open recruiting at present for this section. A limited number of clerk-orderlies is now being enlisted, and these men receive their training at the Royal Army Medical Corps Depot.

INDIAN MEDICAL SERVICE.

THE Indian Medical Service differs from all the other State Services in that it combines the opportunities of a military and a civil career. It is primarily a military service, and all officers on first landing in India are detailed for service with Indian troops in Indian military station hospitals. After a period of military duty, which before the war varied from four to eight years, the majority of officers chose and were transferred to the civil side. While in civil employ they constitute the war reserve for the Indian Army. During the late war practically all officers not occupying administrative posts or filling essential civil duties were called up for military service.

The possibilities of medical and surgical work and the opportunities for research in all directions which the Service affords have always proved of great attraction, though in recent years the Service has lost its former popularity in the medical schools, and for some time prior to the war competition among highly qualified European candidates was not keen. Under the changed conditions in India the pay and emoluments were insufficient, and the terms of service were out of date. The pay, leave pay, pensions, and leave reserve have been increased recently, the Station Hospital system has been introduced, and command allowances and second in command allowances have been granted for charge of hospitals. These reforms have altered the outlook, and if they had been accompanied with a general change in the position of the British official in India, it would have been easy to say that young medical practitioners could join the I.M.S., secure of a competency from the day they receive their commissions ; but it is idle to conceal the fact that the officers of the I.M.S. may suffer, as all the other British officials in India are suffering, from the mutability of the conditions of life. The I.M.S. is bound to be affected as a career by the altered position of the district civil surgeon who used to enjoy private practice, with all its advantages, material and scientific, and who is now more confined to official work and less able to specialise in any line of medicine or surgery. The large and rising percentage of native officers in the Service of course affects the British competitor for commissions.

These things should be recognised as existent, though they do not alter the fact that in the Service a great career is open to one with the properties and keenness. Whatever may be the outlook in civil practice, the science of preventive medicine, medical research, and medical education must remain for a considerable period in the hands of the European, and we should be surprised to learn that any mass of educated native opinion thinks differently. Here, then, are three important fields of work open to the officer of the I.M.S., and if only on their account the career offered by the Service remains a large, interesting and important one.

During the first few years the young officer is trained in Indian military medical organisation. He acquires experience in dealing with the different races and castes which comprise the Indian Army. He learns the language and customs of the country. He familiarises himself with the practice of tropical medicine and surgery, and has leisure to pursue his further studies with time for recreation and sport in any direction his inclination may dictate. During these years he can make up his mind as to any special branch of study, and whether he is desirous of remaining in military employ throughout his service. Specialist appointments are available on both the military and civil sides.

On the civil side, and the majority of officers are civil surgeons in charge of districts and the civil district hospitals, the work is heavy and interesting, the bulk of it being surgery. There is no country in the world which offers better opportunity for the young surgeon once he has acquired the confidence and esteem of the inhabitants. Private practice is permitted, but it may be stated at once that the emoluments from this source, except in the Presidency or large towns, are much reduced. Nevertheless, with the pay as it now exists, plus certain minor allowances, the civil surgeon is in a position to live reasonably in his earlier years, and can expect to be selected for the higher professional posts as a reward of merit, when a lucrative practice may be obtained. I.M.S. officers are eligible for the professorships at the Medical Colleges in Calcutta, Bombay, Madras, Lahore, and Lucknow in the various subjects comprising the medical curriculum. The bacteriological, sanitary and chemical examinerships, and the work asylums and jail departments open out careers of a varied and valuable kind for those who wish to devote themselves to scientific research or specialist work. The bacteriological laboratories and Pasteur institutes at Kasauli, Bombay, Coonoor, Shillong, and Rangoon are splendidly equipped with provision for research workers. In addition to the scales of pay laid down, allowances are granted for service in these different directions.

Under the study-leave rules officers are entitled ring their service to a year's study-leave in England. is period counts as duty, and is in addition to rlough. It is granted on the basis of one month's ady-leave for each year's active service up to a tal maximum of 12 months. Most officers take it two periods of 6 months each, and add it on to their dinary furlough. During the period of study-leave ey are at liberty to pursue courses of approved ady in any country. They receive furlough pay is an additional lodging allowance of 12*s.* a day. e opportunity thus provided for continuing post-aduate studies for a period of six months twice in s service is invaluable both to the individual and e State.

Accelerated promotion of six months to the nk of major is granted to officers for approved ady or for obtaining the higher medical ualifications.

As regards leave, the Secretary of State has underken to increase the leave reserve to 25 per cent. and aintain a 2½ per cent. study-leave reserve in addition. iese percentages when worked up to are considered aple.

The Secretary of State has further undertaken that ficers of the I.M.S. on the military side will receive e same concessions as regards passages as combatant icers, while officers on the civil side will receive the me concessions, if any, as may be granted to other ficers in civil employ.

The rates of basic pay and pensions are given low :—

NEW RATES OF PAY.

(Given in rupees per mensem.)

Year of service.	Basic pay.	Overseas allowance.	Total basic pay and overseas allowance.	Rank.	Year of service.	Basic pay.	Overseas allowance.	Total basic pay and overseas allowance.

S.L.—Selected List.

Charge allowances and second-in-command allowces for station hospitals will be admissible in addition the above rates of pay at the following rates :—

(a) *Charge Allowance.*

	Rs. per mensem.
class hospitals ..	240
l class hospitals ..	180
l class hospitals ..	120
and 5th class hospitals	nil.

(b) *Second-in-Command Allowance.*

	Rs. per mensem.
1st class hospitals ..	120
2nd class hospitals ..	90

All existing general allowances paid to holders of ofessional and bacteriological appointments and rtain other special classes of appointments on the vil side will be maintained.

Indian officers who have joined or may join the rvice after Dec. 1st, 1918, will draw, as from Jan. 1st, '20, pay in accordance with the basic scale, unless ey are already drawing pay at a higher rate, in iich case they will continue to enjoy the benefit that rate for so long as they would otherwise ve done; but they will not receive any further crement until it is due to them under the basic ale.

PENSIONS.

The pension rates as now revised give £400 a year after 17 years' service, increasing to £800 after 27 years' service. Formerly the rate was £300 after 17 years' service, increasing to £700 after 30 years' service.

Pension Rates.

After 17 years' service ..	£400	After 23 years' service ..	£620
,, 18 ,, ..	430	,, 24 ,, ..	660
,, 19 ,, ..	460	,, 25 ,, ..	700
,, 20 ,, ..	500	,, 26 ,, ..	750
,, 21 ,, ..	540	,, 27 ,, ..	800
,, 22 ,, ..	580		

Additional pensions for administrative officers :—

Colonel, after two years' active service as such	£125
After four years	250
Major-General, after one and a half years' active service as such	300
After three years	350

It is quite impossible to foretell how and to what extent the civil side of the I.M.S. will be affected by the Indian Reform scheme, the essence of which is the increasing participation of Indians in the government of the country. None the less, we consider it right to draw the attention of young medical men who are considering joining the Indian Medical Service to this aspect. At the same time we see no reason why the increased coöperation of Indian and European medical officers should not, if a sympathetic attitude is adopted, result in the benefit of both. The number of Indians in the I.M.S. in the days of the competitive examination varied from 8 to 12 per cent. In the two or three years before the war the percentage of successful Indian candidates varied from 12 to 30 per cent. At the present time European and Indian candidates are admitted by nomination in the proportion of 2 Europeans to 1 Indian. A strict system of selection is maintained and permanent commissions are only granted to candidates, whether Europeans or Indians, who have been recommended after a personal interview as suitable and desirable professionally and socially. Practically all the Indian candidates recommended so far have served in the field with distinction and have been recommended by two of their brother officers for the grant of a permanent commission.

A Board of Selection has been appointed in India for the recruitment of permanent officers for the I.M.S. in the manner indicated, consisting of the Director-General, I.M.S., the Director of Medical Services in India, and an Indian Officer, I.M.S. Candidates who may be summoned by the Board for interview will, if considered suitable for appointment, be placed in one of two classes, according as they have or have not received their medical education chiefly in England. The final recommendations as to the former will be made by the Selection Board in England, while the recommendations as to the latter will be sent direct from India to the Secretary of State, who will make appointments to fill the vacancies. The Selection Committee in England, in addition to considering applications from India of candidates who have mainly received their education in England, will review those of the candidates in the United Kingdom, but not the recommendations of the India Committee in regard to candidates educated in that country.

For full particulars intending candidates should apply to the Secretary, Military Department, India Office, Whitehall, London, S.W. 1.

WOMEN'S MEDICAL SERVICE FOR INDIA.

THIS service is open to fully qualified medical women of British or Indian nationality who desire to carry on work in India. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals. Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare; medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Rates of pay are [illegible] follows :—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	English equivalent* per annum.
1 to [illegible]	Rs.100	Rs.450	£440
4 to 6	,,	Rs.500	£480
7 to 9	,,	Rs.550	£520
10 to 12	,,	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600
16 to 18	,,	Rs.700	£640
19 to 21	,,	Rs.750	£680
22 to 24	,,	Rs.800	£720
over 24	,,	Rs.850	£760

* At rupee value 1*s*. 4*d*.

The above rates of pay are not so high as those of the Indian Medical Service. The fact, however, that furnished quarters are provided (these are not provided in the Indian Medical Service) represents an additional Rs.150 per mensem. Moreover, the official duties of the members of the W.M.S. are lighter than those of the I.M.S.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.200 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years. Study-leave on two-thirds pay is granted to the extent of 12 months in the total service. There is a provident fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent. which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Sir Havelock Charles, India Office, Whitehall, London.

AIR FORCE MEDICAL SERVICE.

THE Royal Air Force Medical Service offers a career for medical men which should prove both attractive and interesting. The rates of pay and allowances are good, and a new field of scientific interest is opened up by the manifold problems which the circumstances of aviation produce. The physical and mental fitness for, and reaction to, the varied conditions under which the flying personnel perform their functions provide much scope for research. As promotion to the higher ranks of the Service is to be entirely by selection, and as [illegible] certain proportion of the higher ranks will be reserved for purely scientific, [illegible] opposed to administrative, appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration.

The establishment will consist partly of permanent and partly of short-service officers. Short-service officers will be admitted by direct entry for a period of two years, which may be extended to four years at the discretion of the Air Council on recommendation of the Director of Medical Services. Those who are not selected for permanent commissions will pass into the Royal Air Force Medical Reserve at the expiration of their period of service on the active list, and will then receive the gratuity to which their service entitles them.

Short-service officers who are approved for permanent commissions, but for whom there are not vacancies in the Royal Air Force Medical Service, may, under certain conditions, transfer to the Royal Army Medical Corps, counting their time served in the Royal Air Force towards increments of pay and retired pay in the Royal Army Medical Corps.

Officers who have been selected for permanent commissions will be granted leave for a period not exceeding nine months for post-graduate study in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such leave will be granted during the first six years of permanent service, and during such leave officers will remain on full pay and allowances.

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will be promoted to the rank of Squadron Leader after 10 years' total service. Accelerated promotion may be carried out, in a limited number of cases, of officers who show exceptional ability after the completion of eight years' service. Promotion to the rank of Wing Commander will be by selection at any period after 16 years' total service, and to that of Group Captain by selection at any period after 22 years' service.

There will be no competitive examination on entry; candidates must be under 28 years of age, be nominated by the Dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce—

1. Birth certificate.
2. Medical registration certificate.
3. A declaration containing the following information :—

(*a*) Age and place of birth.

(*b*) That he is of pure European descent, and the son of a subject of the British Empire.

(*c*) That he labours under no constitutional or mental disease or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate in peace or war. (All candidates will be required to pass a medical examination as to their physical fitness before acceptance to ensure that they fulfil the standard laid down in this declaration.)

(*d*) That he is ready to engage for general service at home or abroad as required.

(*e*) The qualifications he is possessed of, and what medical or other appointments he has held (if any).

(*f*) That he is willing to fly whenever called upon to do so, and to qualify in such aviation tests as may be required.

If the applicant is in possession of a certificate of training in an Officers' Training Corps this should be submitted.

An applicant who at the time of application holds, or is about to hold, a resident appointment in a recognised civil hospital may be seconded for the period not exceeding one year, during which he holds such appointment. Whilst seconded he will not receive pay from Air Council funds, but his seniority will count from the day on which he is seconded to the civil hospital.

Uniform and Equipment.

Medical officers will be required to provide themselves with the uniform of their rank and with the distinguishing badges of the Royal Air Force Medical Service. They will be required to provide themselves with service dress and mess dress. The provision of full dress is entirely optional.

An outfit allowance of £50 will be granted to officers if they have had no previous commissioned service.

If they have had previous commissioned service in the Royal Navy, the Army, or the Royal Marines, but not in the Royal Air Force, they will receive an outfit allowance of £25.

Officers on entry are required to provide themselves with the regulation pocket case of instruments.

RATES OF PAY AND RETIRED PAY.

		Principal Medical Officer	1950

The scale of retired pay for Group Captains and lower ranks is given below :—

Age.	Service counting for retired pay.	Rate of retired pay.	Addition for each extra year of service.*	Reduction for each deficient year of service.*
		£	£	£
55	24	790	22	15
54	24	765	22	15
53	23	742	22	15
52	23	720	22	15
51	22	697	22	15
50	22	675	15	15
49	21	637	15	15
48	21	600	15	15
47	20	562	15	15
46	20	525	15	15
45	19	487	15	15
44	19	450	15	15
43	18	412	15	15
42	18	375	15	15
41	17	337	15	15
40	17	300	15	15

* Limited to five years.

Group Captains retire at 55; maximum retired pay £900.
Wing Commanders retire at 51; maximum retired pay £600.
Squadron Leaders retire at 48; maximum retired pay £500.

There will be a minimum qualifying period for retired pay of 20 years.

Gratuities.

Short-service officers will receive gratuities at the rate of £100 for each of the first two completed years of service, and at the rate of £150 for the third and fourth completed year. (If granted permanent commissions these gratuities will not be payable, but the period of service under the short-service commission will count for retired pay.)

Medical officers holding permanent commissions may, at the discretion of the Air Council, be allowed to withdraw from the Service after ten years' service with a gratuity of £1250 or after 16 years with a gratuity of £2000 in lieu of retired pay.

Allowances.

The usual allowances will be payable to medical officers under the same conditions as to officers of other branches of the Royal Air Force.

The dental service of the Royal Air Force is a part of the Army Dental Corps (see p. 419).

COLONIAL MEDICAL SERVICE.

IN the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, and territories under their control, such as Papua and the Cook Islands, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; appointments in Egypt and the Soudan are regulated from the Foreign Office; in Rhodesia the appointments are made by the British South Africa Company, London Wall Buildings, E.C.; in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E.C., for appointments; and those in Sarawak are in the hands of H.H. the Rajah.

As a general rule, each Colony or Protectorate has its own public service distinct from that of every other; and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another. There are two exceptions to this rule: (*a*) The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, is one service. (*b*) In practice the medical services of the Straits Settlements and the Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States or vice versa.

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the Secretary of State for the Colonies are (*a*) the West African—viz., Nigeria, the Gold Coast, Sierra Leone, and the Gambia; (*b*) the East African—viz., the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika Territory; (*c*) the Eastern—viz., Ceylon, the Straits Settlements and Malay States, Hong Kong, Mauritius, and Seychelles; (*d*) the West Indian—viz., British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, British Honduras, and the Bahamas; (*e*) Fiji and the Wester Pacific, Cyprus, Malta, Gibraltar, St. Helena, Bermuda, and the Falkland Islands; and (*f*) Palestine.

In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. Appointments in Malta are all filled locally. Vacancies occur most regularly and frequently in the West African Medical Staff, the East African Medical Service, and the Straits Settlements and Malay States.

All applicants for medical appointments in the gift of the Secretary of State for the Colonies should be between the ages of 23 and 35,[1] and must be doubly qualified; preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and professional competence will be required, and every officer before being definitely appointed will be medically examined by one of the consulting physicians of the Colonial Office: Sir J. Rose Bradford, 8, Manchester-square, London, W. 1; Sir J. Hawtrey Benson, 57, Fitzwilliam-square, Dublin; Lieut.-Colonel J. Arnott, I.M.S., 8, Rothesay-place, Edinburgh; and Dr. R. H. Kennan, 2, St. James's-road, Liverpool. Applications for such appointments must be addressed to the Assistant Private Secretary (Appointments), Colonial Office, Downing-street, S.W. 1.

EAST AFRICAN MEDICAL SERVICES.

Medical officers in the Kenya Colony and Protectorate and the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika

---

[1] In the case of East Africa, preference will be given to candidates who are over 25 years of age. In the case of Fiji and the Western Pacific, preference will be given to candidates who are under 30. At the present time, however, no definite age-limits are insisted on; but officers over the age of 35 must be prepared to serve, if required, on a temporary and non-pensionable footing.

Territory are appointed on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory. Unless the Secretary of State directs to the contrary, they are required to attend a course of instruction at the London or Liverpool School of Tropical Medicine before taking up their appointments. If such a course is not taken before proceeding to East Africa, they are required to take it during their first leave of absence. Medical officers (but not medical officers of health) are permitted to take private practice, on the understanding that they give precedence to their official duties. It must be understood that, as a general rule, additions to their income from this source are not likely to be substantial.

The currency in different Dependencies in East Africa varies. In Kenya, Uganda, and the Tanganyika Territory, an East African shilling (one-twentieth of a pound sterling) is the standard coin. Salaries and sterling allowances are issued locally in respect of resident service at a fixed rate of 20 shillings to the pound sterling. A special local allowance, at the rate of 25 per cent. of sterling salaries and allowances, was to be paid on all salaries and allowances issued in respect of resident service up to March 31st, 1923. After that date the allowance was reduced to an average of 15 per cent. of sterling salaries and allowances issued in respect of resident service, but it is proposed to arrange for the adoption of a sliding scale giving a larger percentage of local allowance on low salaries than on high salaries. The question of the continuance or otherwise of the allowance will be subject to review on March 31st, 1924. In Zanzibar and Somaliland the Indian rupee is the standard coin, and for the present sterling salaries and allowances are issued at a fixed rate of 15 rupees to the pound. No local allowance is paid. In Nyasaland sterling currency is used, and no local allowance is paid.

Medical officers are provided with quarters free of rent (but not of rates or other similar outgoings), if quarters are available; if quarters are not available, the Governor may provide temporary accommodation or alternatively, at the discretion of the Government, an allowance in lieu of quarters calculated at 15 per cent. of the initial salary of an officer's appointment. The salary of a medical officer is £600 per annum, rising by annual increments of £25 to £900 per annum, with efficiency bars at £700 and £800.

Medical officers in East Africa are permitted to retire with gratuity, if they wish, instead of waiting to retire on pension as follows: (*a*) After nine years' service, of which at least six must have been spent in East Africa, £1000; (*b*) after 12 years' service, of which at least eight must have been spent in East Africa, £1250. If an officer elects to retire with gratuity, he thereby forgoes all claim to pension.

The grades and salaries (apart from ordinary medical officers) in the medical departments are as follows :—

Kenya : Principal Medical Officer, £1200 ; Deputy Principal Medical Officer, £1000 ; Principal Sanitation Officer, £1000 ; Resident Surgeon, Nairobi European Hospital, £900–50–1000 ; Senior Medical Officers, £800–25–900 ; Sanitation Officers, £800–25–900 ; Bacteriologist, £900–50–1000 ; First Assistant Bacteriologist, £800–25–900 ; Second Assistant Bacteriologist, same scale as Medical Officer.

Uganda Protectorate : Principal Medical Officer, £1200 ; Deputy Principal Medical Officer, £1000 ; Principal Sanitation Officer, £1000 ; Specialist Officer for Anti-Venereal Measures, £1000 ; Sanitation Officer, £800–25–900 ; Senior Medical Officers, £800–25–900 ; Bacteriologist, £900–50–1000 ; Assistant Bacteriologist, same scale as Medical Officer.

Nyasaland Protectorate : Principal Medical Officer, £1000. Senior Medical Officer, £800–25–900 ; Sanitation Officer, £800–25–900.

Zanzibar Protectorate : Principal Medical Officer, £1000 ; Senior Medical Officer of Health, £800–25–900.

Somaliland Protectorate : Senior Medical Officer, £800–25–900.

Tanganyika Territory : Principal Medical Officer, £1200 ; Deputy Principal Medical Officer, £1000 ; Senior Sanitary Officer, £1000 ; Director of Laboratory, Dar-es-Salaam, £800–25–900 ; Senior Medical Officers, £800–25–900.

The medical officers of health are usually selected from the medical officers in the permanent establishment. They receive special non-pensionable allowances of £50 or £100 a year according to station.

ASIA.

Straits Settlements and Federated Malay States.—European medical officers are appointed on the following scale of salaries: $440 per mensem, rising to $480 per mensem during three years' probation; then, if they are placed on the pensionable establishment, rising to $500 per mensem, and thence by annual increments of $25 per mensem to $800 per mensem, with a strict efficiency bar at $600 per mensem. This scale of salaries has been fixed on the supposition that medical officers join the service at about the age of 27. Above the concluding figure of $800 per mensem there are certain higher appointments as follows: Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $1200 per mensem. Class A: seven posts at $1050 per mensem. Class B: seven posts at $850, rising by $30 to $1000 per mensem.

The following temporary allowances are at present paid to all officers recruited from Europe in the Government Services of the Straits Settlements and Federated Malay States: unmarried officers, 10 per cent. of salary; married officers, 20 per cent. of salary. Private practice by Government medical officers is not allowed. They may, however, do, and receive fees for, consultative work, under conditions approved by the Government. Information about general conditions in Malaya is obtainable from the Malay States Information Agency, 88, Cannon-street, E.C. 4.

Seychelles.—The chief medical officer receives Rs.6000 and Rs.300 in fees. There are two assistant Government medical officers, one receiving Rs.5500 and Rs.500 house allowance, and one receiving Rs.5000. A small permanent increase of 5 per cent. on these salaries has been given as from Jan. 1st, 1921.

Hong-Kong.—The present establishment of the medical department is: principal civil medical officer, £1000–£50–£1200 ; five medical officers, £600–£25–£1000; health officer of the port, £600–£25–£1000 ; second health officer of the port, £600–£25–£1000; bacteriologist, £700–£25–£1000. A temporary allowance on a scale varying with the sterling exchange value of the dollar is at present payable. Salaries are converted locally at the rate of 2*s.* = $1. Free quarters are not provided, but in certain instances a rent allowance is paid by the Government.

AMERICA.

British Guiana.—There are the following posts in the medical service of the Colony: one surgeon-general, £1000 per annum, with consulting practice; one bacteriologist and pathologist, £450–£700 (increment £50), with £50 allowance in lieu of fees; six medical officers at £900 ; eight medical officers at £600–£700 ; 20 medical officers at £500–£600. Some of the senior posts also carry duty allowances (varying from £50 to £300 per annum) and quarters. All the junior appointments in which private practice is not allowed carry duty allowances. Private practice is allowed in certain cases.

Trinidad and Tobago.—In Trinidad and Tobago there are over 40 appointments. Under the terms of the Ordinance regulating the medical service, officers are appointed in the first instance on two years' probation as supernumeraries and are eligible for appointment as Government medical officers at the end of this period. Supernumeraries receive a salary of £400 per annum with furnished quarters, and are usually attached to the Government hospital. Government medical officers receive salary at the rate of £400 per annum with annual increments of £25 accruing from the date of first appointment as supernumerary medical officers, until reaching the maximum of £600. Most are employed as district medical officers, with private practice, a residence or a rent allowance of £50, a horse allowance or motor allowance averaging £110 (except in one district). Officers employed in institution work receive allowances in lieu of private practice varying from £50 (and furnished quarters) to £300. In no case therefore do the emoluments on first appointment amount to less than £550 a year and furnished quarters. In a few districts a system has been introduced by which the work is performed by private practitioners under temporary contracts. There is good scope for private practice in all medical districts. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent).—There are over 25 appointments. The colonial surgeon, Grenada, receives £650–£800. The chief medical Officer, St. Lucia, receives £600–£700 plus forage and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government vary from £315–£420, and with allowances in certain cases. The Governor has the power to transfer a medical officer from one island to another at his discretion. The appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The appointments are of the same nature as in the Windward Islands and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary varying from £312 to £400, according to station, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands, and in certain districts may be required to perform magisterial duties. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also as a rule, allowed private practice. The chief medical officer, St. Kitts, receives £700–£25–£750 without private practice.

British Honduras.—There are seven medical appointments (besides the principal post of colonial surgeon) at a salary of $2430 per annum. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The value of the dollar is approximately the same as that of the United States dollar.

OTHER OVERSEAS APPOINTMENTS.

Fiji and the Western Pacific.—In Fiji the Government medical officers receive a salary of £400, rising by annual increments of £25 to £600, with partly furnished quarters, or a house allowance of £50. In some districts a medical officer is also a district commissioner, with an additional allowance of £150. They are allowed private practice, on the understanding that their official duties are not neglected. Private practice, however, cannot be guaranteed, and in most districts it is very small in amount. Where no private practice exists, a duty allowance of £50 is granted. They are required either to take charge of hospitals or of districts, at the discretion of the authorities. The posts are pensionable.

In addition to a chief medical officer (£800 a year, rising to £1000), a resident medical officer, Colonial Hospital (£650–£900, inclusive of allowances as medical officer of health and officer in charge of the Medical School), and a medical superintendent, Makogai Leper Asylum (£600 rising to £800), there are in Fiji 11 medical officers, five of whom are also district commissioners. The staff in the British Solomon Islands Protectorate consists of one senior medical officer (£650 rising to £750) and two medical officers (£550 rising to £650). In the Gilbert and Ellice Islands Colony there is one medical officer in charge (£650 rising to £750). Officers may be transferred from Fiji to the Western Pacific at the discretion of the Secretary of State.

Cyprus.—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £900, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s.* per diem forage allowance. There is also a medical officer of health on £600, rising by £20 increments to £720 without private practice; these are the only medical appointments in the island which are open to English candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £750, and private practice. There are also two assistant surgeons with a salary of £720 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The colonial surgeon at present receives £300 per annum, £20 fees as health officer, and £30 horse allowance. Private practice is allowed. A temporary bonus of 20 per cent. is at present being paid to the colonial surgeon, who further receives an allowance of £67 per annum from the Administration. The assistant colonial surgeon at present receives £550 a year and a horse allowance, but the salary may be revised on the occurrence of a vacancy. No private practice without special permission of the Governor.

Falkland Islands.—There are two appointments. The colonial surgeon is paid at the rate of £600 per annum, with free furnished quarters. The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters. Private practice is shared between the colonial surgeon and the assistant colonial surgeon. The office of colonial surgeon is pensionable.

Palestine.[2]—The grades and salaries of superior appointments in the Department of Health are: Director, £E1100–50–1400, plus £E100 expatriation allowance. Deputy director, assistant director (laboratory section), and principal medical officer (Jerusalem district) £E800–50–1100 plus £E100 expatriation allowance. Deputy assistant director, chemical analyst, assistant bacteriologist and entomologist, four principal medical officers (remaining three districts and railway staff), and assistant principal medical officer (Jerusalem district) £E550–25–750 plus £E50 expatriation allowance. The remainder of the staff is recruited locally.

LEAVE AND PENSIONS.

Leave and Passages.—Leave of absence in East Africa on full salary is granted in the normal case after a tour of residential service (of not less than 20 and not usually more than 30 months) to an amount of five days for each completed month of residence (or 2½ days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro, for which full pay is also given. Officers serving in Uganda, Zanzibar, and the Tanganyika Territory, or in certain stations in Kenya and Nyasaland, are allowed six (or three) days' leave in respect of each month of service instead of five (or 2½) days' leave respectively. In Somaliland special leave regulations exist which provide for an officer taking leave after a shorter tour of service than in other parts of East Africa. Free first-class passages are provided for the officer on first appointment and on leave.

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half-pay may be granted on special grounds. Up to the end of 1923 free passages are granted on first appointment and on leave, but the continuance of this privilege beyond that date is uncertain; but free passages on first appointment or transfer are granted permanently for officers with salary under £800 per annum.

---

[2] £1 Egyptian (of 100 piastres) is equivalent to £1 0*s.* 6*d.* sterling.

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of six years' resident service without any special grounds. It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months[3] in any two years. In British Guiana officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay leave may be taken in addition to six months' full-pay leave.

On first appointment an officer whose salary and fees together do not exceed £800 a year will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. An officer taking leave out of the Colony has in most cases to provide his own passages.

Pensions.—Officers on the pensionable establishment retire on attaining the age of 50 years or after 20 years' East African service, whichever is earlier; but they may be retained in the Service, with their own consent, for such further period as the Government may recommend. Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-sixtieth of pensionable emoluments —i.e., salary and value of free quarters[4]—at the time of retirement, two years' service being reckoned as three years for this purpose, subject to an average of emoluments for the last two years before retirement instead of the actual emoluments at the time of retirement being taken as the basis for calculation in certain circumstances.

In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half-pay as half service. In a few cases the retiring age is 60 and the pension after ten years' service is ten-sixtieths instead of fifteen. In the Straits Settlements and Malay States, an officer may, with the consent of Government, retire at age 50. Pensions are calculated on a basis of length of service in months instead of years.

WEST AFRICAN MEDICAL STAFF.

Applicants for appointment as medical officers in the West African Medical Staff (the higher grades will usually be filled by promotion from the lower) must be British subjects of European parentage and between 23 and 35 years of age; preference is given to candidates who are over 25 years of age. Applicants must possess a complete double qualification, and must be on the Medical Register. Passages for wives and children are not provided by the Government, and houses for the wives of junior medical officers are rarely available. Officers are not allowed to take their wives and young children out with them until they have acquired experience of the local conditions and have obtained the sanction of the Governor; and permission to bring out young children will only be given in the most exceptional circumstances.

Candidates whom it is proposed to select for appointment will have to be medically examined by one of the medical advisers of the Colonial Office (or, in the case of those residing in a Colony, by a medical officer appointed by the Colonial Government), and no appointment will be made unless the candidate is declared to be physically fit for service in West Africa. Candidates are allowed to express a preference for any particular Colony or Protectorate, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony or Protectorate at the discretion of the Secretary of State. Candidates who wish to be posted to the Northern Provinces of Nigeria should be able to ride. Transfers from one Colony or Protectorate to another will be made as seldom as possible. They should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred elsewhere, as the number of such transfers is exceedingly small.

Officers of the West African Medical Staff who may be transferred to pensionable appointments under the Crown elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided that they have been members of the staff for at least 12 months. Every officer selected for appointment is required to have himself revaccinated before proceeding to West Africa, unless one of the medical advisers of the Colonial Office certifies in any particular case that this is unnecessary.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for two or three months, either at the London School of Tropical Medicine, Endsleigh-gardens, Euston-square, N.W. 1, or at the Liverpool School of Tropical Medicine, University, Liverpool. The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £3 a week will be paid to them monthly in arrear for this purpose. A daily allowance of 5*s.* (but no salary) will be paid to each candidate monthly in arrear during the course, and may be continued subsequently up to the date of embarkation. He will be bound to refund them (1) if he declines to accept an appointment in any of the Colonies or Protectorates for which he may be selected by the Secretary of State; (2) if he fails to obtain a certificate in regard to progress and efficiency, or (3) if he relinquishes the West African Service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of the date of his arrival in West Africa.

If at the end of the session there exists no vacancy in the Staff to which a candidate can be appointed, he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy.

Leave of Absence.—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United ingdom, and, if the officer is returning to West frica for further service, the time necessarily taken n the journey from the United Kingdom to the olony. Vacation leave may be granted without any pecial grounds after 18 consecutive calendar months of esidential service in West Africa. An officer will ot be required to serve a tour of more than 24 onsecutive calendar months' residential service xcept in special circumstances; and the Governor ay grant vacation leave to any officer at any time fter he has completed 12 consecutive calendar onths' residential service. Vacation leave on full alary may also be granted to an officer if he is invalided om West Africa after less than 12 consecutive alendar months' residential service, and sick leave n full salary may be granted for any period not xceeding six calendar months.

---

[3] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years.

[4] The value of free quarters for pension purposes is normally taken as 15 per cent. of the minimum salary of the grade in which [illegible] officer is serving at the time of retirement; but [illegible] a special temporary concession it will be taken [illegible] 30 per cent. of such salary in the cases of officers retiring on or after Jan. 1st, 1922. This arrangement will be liable to review after it has been in force for two years.

Appointments and Salaries.—The Medical Services f the West African Colonies and Protectorates—amely, the Gambia, Sierra Leone, the Gold Coast ncluding Ashanti and the Northern Territories), and igeria (Southern and Northern Provinces)—form one ervice under the name of the West African Medical taff. All the medical officers for the service are elected by the Secretary of State for the Colonies, nd are on one list for employment and promotion. he grades and emoluments of the Staff are at present s follows:—

The Director of the Medical and Sanitary Service, Nigeria, eceives a salary of £1800 a year, with a duty allowance at he rate of £360 a year. The Director of Medical and anitary Service in the Gold Coast receives a salary of 1600 a year, with a duty allowance at the rate of £320 a ear. The Director of Medical and Sanitary Service in ierra Leone receives a salary of £1400 a year, with a duty llowance at the rate of £280 a year. The Deputy irector of Medical and Sanitary Service, Nigeria, and the eputy Director of Sanitary Service, Nigeria, receive salaries f £1500 a year, with duty allowances at the rate of £300 a ear. The Deputy Director of Medical and Sanitary Service, old Coast, receives a salary of £1400 a year, with duty allowance at the rate of £280 a year. Assistant Directors Medical ervice: There are nine appointments on this grade, six in igeria, two in the Gold Coast, and one (with the title of eputy Director Medical Service) in Sierra Leone. The alary is at the rate of £1300 a year, with duty allowance at he rate of £260 a year. The Assistant Director of Sanitary ervice, Nigeria, the Deputy Director of Sanitary Service in he Gold Coast and the Deputy Director of Sanitary Service n Sierra Leone receive salary at the rate of £1300 a year, ith duty allowance at the rate of £260 a year. Specialists: he number of these appointments is not fixed, officers of utstanding professional merit being eligible for appointment. he salary is at the rate of £1300 a year, with duty allowance t the rate of £260 a year. After five years' approved service s such, the specialist officer is eligible to receive a salary at e rate of £1400 a year, with duty allowance at the rate of 280 a year. There are at present four officers appointed pecialists in Nigeria and two in the Gold Coast. Senior ledical Officer: There are twenty appointments of this rade, with salary at the rate of £1000 a year, rising by nnual increments of £50 to £1150 a year, and seniority llowance at the rate of £100 a year. The Senior Medical fficer, Gambia, is allowed "staff pay" of £150 a year, in ddition to duty allowance, but he is debarred from private ractice. Senior Sanitary Officer: There are six appointents of this grade, with salary at the rate of £1050 a year, sing by annual increments of £50 to £1200 a year, and a uty allowance at the rate of £210 a year. Medical Officer: he salary attached to this grade is at the rate of £660 a year, sing by annual increments of £30 to £720 a year. Then, confirmed in the appointment, £720 a year, rising by nnual increments of £40 to £960, with seniority allowance at e rate of £72 a year. Before passing £800, medical officers e required to take a special course of study for three months. they obtain satisfactory certificates at the end of the ourse they draw their further increments up to £960 a year.

A medical officer who has served for three years on e maximum salary of this scale (£960) without btaining promotion is eligible, if recommended by e Governor, to be placed on the scale £1000–£50–1150, with £100 seniority allowance (as for Senior ledical Officers).

Special Appointments.—The director of the Medical esearch Institute, Lagos, and the pathologist, Accra, eceive a salary of £1300 a year, with a duty allowance £260 a year, rising after five years' approved service to a salary at the rate of £1400 a year and duty allowance at the rate of £280 a year. Salary at the rate of £800 a year, rising by annual increments of £40 to £960 a year, is attached to about ten posts (those of assistant at the Medical Research Institute, Lagos, and medical officers of health at various places), irrespective of the seniority of the officer holding the appointment. In addition to the seniority allowance (£72 a year), staff pay at the rate of £150 a year is also attached to these posts; and the holder of the appointment draws half of the staff pay during leave of absence, the remainder being drawn by his locum tenens. The holders of these appointments are not allowed private practice.

Duty allowances, seniority allowance, and staff pay are not pensionable emoluments.

Increments.—Increments to salaries are payable only when the service of an officer during the period of employment qualifying for increment is approved.

Payment of Salaries.—Information as to the payment of officers' salaries or of monthly remittances to persons in England may be obtained from the Crown Agents for the Colonies, 4, Millbank, S.W. 1. All allowances are paid locally.

All officers of the staff, except directors, deputy directors, assistant directors, senior sanitary officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at the majority of stations, and no guarantee can be given that an officer will be posted to a station in which he will be able to practise privately. As a general rule, and subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the Staff.

Pensions and Gratuities.—Pensions and gratuities on retirement from the service are granted in accordance with the law and regulations of each individual Colony.

Fuller information can be obtained from the Private Secretary, Colonial Office, Whitehall, London, S.W. 1.

DIPLOMAS IN TROPICAL MEDICINE.

ALTHOUGH a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Tropical Medicine, 5, Endsleigh-gardens, London, N.W. 1 (founded in 1899), which is a school of the University of London in the Faculty of Medicine.

University of Cambridge.—Two Examinations in Tropical Medicine and Hygiene are conducted yearly by the State Medicine Syndicate of the University of Cambridge. The examinations are held in Cambridge early in August and at the end of December. Each examination will extend over four days.

Any person whose name is on the Medical Register is admissible as a candidate to the examination provided (I.) that a period of not less than 12 months has elapsed between his attainment of a registrable qualification and his admission to the examination; (II.) that he produce evidence, satisfactory to the Syndicate, that he has diligently studied Pathology (including parasitology and bacteriology) in relation to Tropical Diseases, Clinical Medicine, and Surgery at a Hospital for Tropical Diseases, and Hygiene and Methods of Sanitation applicable to Tropical Climates. As evidence of study and attainments a candidate may present to the Syndicate (1) any dissertation, memoir, or other record of work carried out by himself on a subject connected with Tropical Medicine or Hygiene; (2) any Certificate or Diploma in Public Health or Sanitary Science he may have obtained from a recognised Examining Body. Such evidence will be considered by the Syndicate in determining whether he is qualified for admission to the examination and by the examiners in determining whether, if admitted, he shall be included in the list of successful candidates.

The examination will be partly in writing, partly oral, and partly practical and clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment), and will have reference to the nature, incidence, prevention, and treatment of the epidemic and other diseases prevalent in tropical countries. Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma (D.T.M. & H.) testifying to his knowledge and skill in tropical medicine and hygiene.

The fee for the examination is £9 9*s.*, and applications should be addressed to Dr. Graham-Smith, Medical Schools, Cambridge.

University of London.—The M.D. degree may be taken in tropical medicine at an examination held twice annually, for which a thesis may be submitted.

University of Liverpool.—The University grants a Diploma in Tropical Medicine. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The subjects of examination are (*a*) Tropical Pathology, Parasitology and Entomology; (*b*) Tropical and Applied Bacteriology; (*c*) Tropical Hygiene and Sanitation; (*d*) Tropical Medicine, including Ætiology, Symptoms, Diagnosis, and Treatment of Tropical Diseases. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. The fee for the full course of instruction is £21, with an extra charge of 10*s.* 6*d.* for the use of a microscope if required. Applications should be made to the Dean of the Medical Faculty, University of Liverpool. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The diploma of D.T.M. & H. Eng. is awarded on the results of an examination held thrice yearly in January, April, and July. Candidates must possess a registrable qualification, and produce evidence of having attended (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine in a recognised institution during not less than three months, (2) clinical practice of a recognised hospital for the same period. Conditions of study may be modified in the case of candidates of special experience. Fee for admission to the examination, £9 9*s.*, 14 days' notice of entry to the Secretary, Examination Hall, Queen-square, London, W.C. 1.

DIPLOMA IN OPHTHALMIC MEDICINE.

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.—The diploma in ophthalmology (D.O.) is granted to registered medical practitioners after passing an examination, held annually in July, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in January and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a registrable qualification. Fee for admission, £6 6*s.*

DIPLOMAS IN PUBLIC HEALTH.

As usual we include in the Students' Number of The Lancet an epitome of the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene or State medicine, as this discipline is variously called. Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council from 1902 to 1911. The new regulations, which come into force on Jan. 1st next, extend the period of study and postpone the granting of a diploma until at least two years from qualification.

Conjoint Board of the R.C.P.Lond. and R.C.S.Eng.—The following are the regulations for obtaining the Diploma in Public Health: The examination consists of two parts. The first part of the examination takes place in January and July, and the second part in January and July. The fee for each part is £10 10*s.*, except for those who are diplomates of the Royal Colleges, who pay £6 6*s.* for each part. A candidate intending to present himself must give 14 days' written notice to the Secretary, at the Examination Hall, Queen-square, London, W.C. 1. He will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification for at least 12 months; and (2) of having attended thereafter practical instruction in a laboratory recognised by the Examining Board in England for at least 240 hours during a period of six months. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been diligently engaged in acquiring a practical knowledge of Public Health administration during six months, which may be reduced to three months under certain specified conditions; and (2) of having attended during three months the clinical practice of a hospital for infectious diseases.

New regulations requiring a more extended course of special study will come into force on Jan. 1st, 1924, which will apply to all candidates who have not commenced bonâ-fide study of Public Health in accordance with the above regulations before that date. They are as follows: The Examination consists of two Parts. Part I. will be held in the months of January, April, and June, and Part II. in the months of January, April, and July in each year. Candidates may enter for Parts I. and II. separately or at the same time, but they must pass Part I. before proceeding to Part II. The Examination in each part will be written, oral, and practical. Part II. will include a practical examination in Infectious Diseases, Food Inspection, and Inspection of selected Premises. The Fee for admission to each Part of the Examination, which must be paid three days before that part commences, is £10 10*s.*, except in the case of Candidates who possess the Licence, Membership, or Fellowship of the Royal College of Physicians of London, or the Membership or Fellowship of the Royal College of Surgeons of England, who will be required to pay £6 6*s.* only for each part. Candidates who fail to satisfy the Examiners in either part may present themselves again at the next Examination on payment of the same Fees. Candidates intending to present themselves for either part of the Examination must give 14 days' notice in writing to the

Secretary, at the Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

Candidates will be admissible to Examination in Part I. on producing evidence :—

1. Of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery.

2. Of having attended during [illegible] period of not less than ive months at an Institution recognised by the Examining Board in England, practical instruction in (*a*) Bacteriology and Parasitology (including Medical Entomology) especially n their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work. (*b*) Chemistry and Physics in relation to public health, during 90 hours, of which not less than 70 hours have been occupied in practical aboratory work. (*c*) Meteorology and Climatology in relation to public health, during not less than 10 hours.

Candidates will be admitted to Part II. of the Examination on producing evidence :—

1. Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less than two years, of being registered by the General Medical Council, and of having completed the curriculum for the Diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification.

2. Of having attended, after obtaining the registrable Qualification, instruction during not less than 80 hours at an Institution recognised by the Examining Board in England in the following subjects :—(*a*) The Principles of Public Health and Sanitation for not less than 30 hours ; *b*) Epidemiology and Vital Statistics for not less than 20 hours ; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours ; *d*) Sanitary Construction and Planning during not less than 10 hours.

3. Of having attended for three months the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England and of having therein received nstruction in the methods of administration. This course must include 30 daily attendances of not less than two hours n each week.

4. Of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a Medical Officer of Health, and of having received, from such officer or other competent Medical Officer during not less than three hours on each of 60 working days, practical instruction in those duties and also those relating to : (*a*) Maternity and Child Welfare Service ; (*b*) Health Service for children of school age ; *c*) Venereal Diseases Service ; (*d*) Tuberculosis Service ; *e*) Industrial Hygiene ; (*f*) Inspection and Control of Food, ncluding meat and milk.

The above certificate (4) must be obtained from a Medical Officer of Health who devotes his whole time to public work, or from a Medical Officer of Health of a Sanitary Area having a population of not less than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

University of Oxford.—An examination, conducted partly in writing, partly vivâ voce, and in each subject partly practical, is held in Michaelmas and Trinity Term in the following subjects :—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately ; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £10 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise *a*) written papers of three hours each in (i.) Chemistry and Physics, and (ii.) Pathology and Bacteriology ; *b*) a three hours' practical and vivâ voce examination n Chemistry and Physics ; (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacterioogy.

The Second Part of the Examination will consist of the following parts :—(*a*) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health) ; (*b*) a practical and vivâ voce examination in General Hygiene ; and (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce certificates (1) of Laboratory Work in Chemistry as applied to Hygiene, and (2) of having had Practical Instruction in Bacteriology, and the Pathology of the Diseases of Animals transmissible to Man.

Candidates in Part II. will produce the following further certificates : (3) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration ; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration.

All the above degrees are now open to Women Students, and particulars of Scholarships, &c., may be obtained from the Principals of the various Ladies' Colleges. The names of candidates for the Diploma in Public Health must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford, to whom applications for any further information should be addressed.

University of Cambridge.—Two examinations in so much of State medicine as is comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be ora and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option ; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) general principles of hygiene ; (2) bacteriology ; (3) chemistry in Part I. of the examination ; or (4) the second part of the examination, which has reference to State Medicine and to the applications of Pathology and Sanitary Science. Every candidate will be required to pay a fee of £6 6*s*. before admission or readmission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be readmitted to either part on payment of a fee of £5 5*s*. Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provision (4), above mentioned.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University on Hygiene, Chemistry, &c., and on Bacteriology, and a special course on Protozoal Diseases and on Animal Parasites. For Part II. the Medical Officer of Health for Cambridge gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital, and the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology, Vital Statistics, &c. These courses are open to non-members of the University.

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England.

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Chemical Laboratory, Pembroke-street, Cambridge.

University of London.—Candidates for the M.D. degree may offer State medicine as a subject in which to graduate. They must send to the Academic Registrar with their forms of entry certificates (i.) of having, subsequently to having obtained a registrable qualification to practise Medicine, attended a course of practical instruction in a laboratory or laboratories, British or foreign, approved by the University, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught ; such course to extend over a period of not less than six months and to consist of at least 240 hours, of which not more than one-half shall be devoted to practical chemistry. (ii.) *Either* of having, subsequently to having obtained a registrable qualification to practise Medicine, during six months (of which at least three months shall be distinct and separate from the above-mentioned period of laboratory instruction) been diligently engaged on not less than 60 working days in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a person recognised by the University as entitled to grant certificates. *Or* of having held for a period of not less than three years an appointment as Medical Officer of Health of a Sanitary District within the British Dominions, and having a population of not less than 15,000. (iii.) Of having, subsequently to having obtained a registrable qualification to practise Medicine, attended at least twice weekly during a period of not less than three months a practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. In connexion with this degree the various metropolitan medical schools hold regular classes under teachers of Public Health and Sanitary Science, such instruction being also used to obtain the various diplomas of other Universities and of those Royal Corporations which grant them.

University of Durham.—Candidates for the degree of Bachelor of Hygiene (B.Hy.) must be at least 22 years of age, registered, and a graduate in Medicine of a recognised university. They must spend six months at Newcastle-upon-Tyne studying Comparative Pathology, Practical Bacteriology, Sanitary Chemistry, and Physics, and have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is £10 10*s.* and for the degree £6 6*s.* Candidates for the degree of Doctor of Hygiene (D.Hy.) shall be Bachelors of Hygiene of two years' standing, and shall be required to satisfy the Examiners that they have conducted original research in the subject of Public Health. The fee for the examination for the degree of D.Hy. is £20 and for the degree £10. The regulations for examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination is £10 10*s.* and for the diploma £3.

Victoria University of Manchester.—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £8 8*s.*, and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £4 4*s.* Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin about the middle of March and the middle of July in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £6 5*s.* Medical Officers of the Royal Navy who have attended courses in Hygienic Chemistry, Bacteriology, and Public Health at the Naval Medical School, Greenwich, will be admitted to the examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the Staff College and pursued the further course of study approved by the General Medical Council.

Revised regulations take effect as from Oct. 1st, 1923, for B.Sc. and D.P.H., Birmingham.

University of Liverpool.—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The courses may be taken out at any time, and students are allowed to work daily in the laboratories. Composition fee for M.H. and D.P.H., £40 per session.

University of Leeds.—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates may present themselves for Part I. (Sections 1 and 2), Part I. (Sections 3, 4, and 5), and II. separately or at the same time, provided that no candidate be allowed to pass in Part II. unless he has already passed in Part I. Fees.—The fee for each part is £6 6*s.*, and for any subsequent examination in the same part £4 4*s.* Instruction in Sanitary Chemistry and Bacteriology is given in the second and third terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Dean of the Medical School. The Regulations for this Diploma are at present under review in connexion with the recommendations of the General Medical Council.

University of Bristol.—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than two years' standing as such, and shall have passed the examination prescribed by regulation. The examination is divided into two parts.

University of Edinburgh.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. A Diploma in Tropical Medicine and Hygiene is also granted. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction

Physics and Geology in some Scottish University. andidates are not admitted to the Second Examination sooner than six months after having passed the irst Examination, nor sooner than 18 months after aving taken their degree in Medicine, and they must ave attended two separate courses in Public Health some University of the United Kingdom or in such edical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh niversity, each course consisting of 40 lectures at ast ; one of which courses shall deal with medicine nd the other with engineering, each in its relation o public health. The subjects of examination include aboratory work, Physics, Geology, Medicine in its pplication to Public Health, Sanitation, Sanitary aw, and Vital Statistics. Graduates who have held he degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer hemselves for the degree of D.Sc. in Public Health that University. They must then present a hesis and pass an examination in Public Health. he fees are £4 4*s*. for the First and £5 5*s*. for the econd B.Sc. Examinations, and £15 15*s*. for the egree of D.Sc.

University of Aberdeen.—The Diploma in Public ealth (D.P.H.[1]) is conferred only on graduates in edicine of a University in the United Kingdom not ss than 12 months after medical graduation. Every andidate must produce evidence of having complied ith the following requirements: (1) A course or ourses of instruction consisting of not fewer than) meetings dealing with public health in relation o the administrative and other duties of a medical ficer of health, such course or courses to be given y a teacher or teachers in the department of public ealth of a recognised medical school. (2) Practical struction within a laboratory or laboratories pproved by the University, in (*a*) Bacteriology,) Physics and Chemistry, (*c*) Parasitology, such struction to extend over not less than six months two academic terms. (3) Practical Instruction, linical and Administrative, within (*a*) a hospital for eneral infectious diseases—not less than thrice eekly ; (*b*) a hospital or sanatorium or treatment entre for tuberculosis—not less than once weekly ;) a hospital or treatment centre for venereal diseases -not less than once weekly ; such instruction in each roup to extend over three months. (4) Practical struction and experience during not less than three onths in the duties, routine and special, of public ealth administration, under the personal supervision a medical officer of health or other medical officer, , alternatively, that the candidate has held, within he British Dominions, for a period of not less than hree years, an appointment as medical officer of health a sanitary district with a population of not less than 5,000. (5) Practical instruction in : (*a*) Mother and hild Welfare at a Centre or Centres in a Welfare cheme conducted or approved by a Local or Sanitary uthority—not fewer than ten meetings ; (*b*) School ygiene and Medical Inspection of School-children—ot fewer than six meetings ; (*c*) Drawing and Interpretation of Plans—not fewer than six meetings. he fee for the examination is £4 4*s*. for each part, £8 8*s*. for the whole examination.

University of Dublin (*Trinity College*).—The Diploma Public Health is conferred, after examination, on he following conditions. The candidate must be a egistered medical practitioner and have obtained a egistrable qualification at least two years before he second part of the examination. The candidate ust have completed, subsequently to obtaining a egistrable qualification, five months' practical struction in a chemical and bacteriological laboratory, or laboratories, approved by the University, ust have studied practically outdoor sanitary work or six months under an approved officer of health, nd must have attended for three months at a fever ospital where opportunities are afforded for the study of methods of administration. A special prospectus and a list of recognised laboratories may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously ; (*b*) shall have pursued an approved course of study in the Faculty of Medicine ; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology ; (2) Bacteriology ; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held in two parts, in March and in June. The first part of the examination will have reference to the general principles of sanitary science and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 1 guinea.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Bacteriology in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer ; and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics and Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination, and intimation is made that the curriculum and examination will be adjusted to meet the requirements of the regulations of the General Medical Council which come into force on Jan. 1st, 1924. Candidates applying for Regulations should state date of commencement of curriculum. The Registrar for Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and for Glasgow Mr. Walter Hurst, 242, St. Vincent-street.

---

[1] New Regulations for the Diploma in Public Health are at esent under consideration.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.—Every candidate for the Diploma in Public Health must be a registered medical practitioner. He must subsequently to qualification (1) receive four months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months practically study outdoor sanitary work under a medical officer of health, and shall as an additional requirement attend a hospital for infectious diseases. Candidates are examined on four days, commencing on the first Monday of February, May, and November. The examination comprises the following subjects: Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Sanitary Law, and Bacteriology. The fee for the examination is £10 10*s*. For further particulars apply to Alfred Miller, O.B.E., Secretary, Committee of Management; Office, Royal College of Surgeons, Dublin.

The Universities of Sheffield, Wales, and St. Andrews also grant a Diploma in Public Health, and the University of Glasgow confers the B.Sc. and D.Sc. in Public Health.

DIPLOMA IN RADIOLOGY.

IN June, 1919, the University of Cambridge instituted a Diploma in Medical Radiology and Electrology to be taken by medical graduates after a course of study extending over a period of six months or more. The lecture course in Part I. consists of physics and electro-technics with photography; in Part II. of radiology and electrology—in each case with special reference to diagnosis and treatment. Six months' clinical experience is required in the electrical department of a recognised hospital. Lecture courses are arranged twice a year alternately in Cambridge and in London. Apart from examination, a diploma may be granted to a medical practitioner of not less than ten years' standing and five years' experience in radiology on presentation of a dissertation. Application to the Secretary, Dr. Shillington Scales, Medical Schools, Cambridge.

UNIVERSITY OF LONDON.—On August 14th Mr. G. G. Gillam was elected to the Epsom Scholarship tenable in the Faculty of Medical Sciences at University College, London.

FORMALDEHYDE.—The Board of Trade announces that under the Safeguarding of Industries Act, Part I. (Arbitrations under Section 1, Subsection 5), the referee has given his decision in the matter of a complaint under the above subsection that formaldehyde has been improperly included in the lists of articles chargeable with duty under Part I. of the Act. The referee has awarded that formaldehyde be excluded from the lists, and the withdrawal will take place as from August 20th.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but it is of eminent advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available.

THE DENTAL BOARD OF THE UNITED KINGDOM.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly-constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts.

The Dental Board consists of a chairman and 12 members; the following are their names and sources of appointment: Chairman of the Board: Rt. Hon. F. Dyke Acland, appointed by the Privy Council. Members of the Board: Mr. L. G. Brock, Mr. W. H. Dolamore, M.R.C.S., L.D.S., and Mr. W. H. Gilmour, M.R.C.S., L.D.S., appointed by the Minister of Health; Mr. D. M'Coig Cowan, M.P., and Mr. William Guy, F.R.C.S.E., L.D.S., appointed by the Scottish Board of Health; Mr. James H. Stirling and Mr. Edward L. Sheridan, F.R.C.S.I., L.D.S., appointed by the Lord Lieutenant of Ireland; Mr. H. J. Waring, Sir James Hodsdon, and Sir Arthur Chance, appointed by the General Medical Council; Mr. John Butterfield and Mr. H. A. Robertshaw, appointed by the Privy Council. Treasurers of the Board: Mr. H. J. Waring and Mr. W. H. Dolamore.

The offices of the Board are at 44, Hallam-street, London, W. 1, adjoining the offices of the General Medical Council.

REGISTRATION OF DENTAL STUDENTS.

The following are the General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923.

The Council recommends that, subject to such exceptions as the Council may from time to time allow, every dental student at the commencement of his studentship should be registered in the manner and under the conditions hereinafter set forth.

1. The registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and is subject to the same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence by pupilage with a registered dental practitioner.

2. Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in mechanical dentistry (see No. 3 below).

3. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school.

4. Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study.

5. The necessary instruction in dental mechanics, or any part of it, may be taken by the dental student either before or after his registration as a student. When a student can show evidence of regular pupilage in dental mechanics to a registered

practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations (see No. 3 above).

List of Schools of Dentistry at which Dental Study may be Commenced.—Birmingham Dental Hospital. Bristol: Royal Infirmary, General Hospital. Dublin: Dental Hospital of Ireland. Dundee: Dental Hospital. Edinburgh Dental Hospital. Glasgow Dental Hospital. Leeds Dental Hospital. Liverpool Dental Hospital. London: Guy's Hospital Dental School, London Hospital Dental School, National Dental Hospital, Royal Dental Hospital. Manchester Dental Hospital. Newcastle-upon-Tyne Dental Hospital. Sheffield Royal Hospital. The Royal College of Surgeons in Ireland. The Dental department of any University of the United Kingdom.

THE EXAMINING BODIES IN DENTISTRY.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have passed the required Preliminary Examination in General Education before Jan. 1st, 1923.

Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. 1. Preliminary Science Examination.—This is identical with Part I. of the First Examination of the Examining Board in England. Candidates who commenced professional study on or after Oct. 1st, 1913, must pass the Preliminary Science Examination before commencing the courses required for the Second Professional Examination. 2. The First Professional Examination.—The candidate must produce evidence of instruction in Dental Metallurgy and Practical Dental Mechanics. The Examination consists of Part I. (Mechanical Dentistry), Part II. (Dental Metallurgy), the examination in Dental Metallurgy being by written paper, and Part III. (*a*) General Anatomy and Physiology, (*b*) Dental Anatomy and Physiology conducted by papers and vivâ voce examination. The parts may be taken together or separately. 3. The Second Professional Examination.—This is divided into two parts: (*a*) the General, (*b*) the Dental. The General part must be passed before the Dental portion. The instruction is obtained partly at a General Hospital and partly at a Dental Hospital. The Second Professional Examination consists of: Part I., General Surgery and Pathology; Part II., Dental Surgery and Pathology, and Practical Dental Surgery. There is a written and vivâ voce examination in each part and a practical examination as well in Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in Medicine or Surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and University above mentioned. The fee for the diploma is 20 guineas, and is payable as follows: Preliminary Science Examination, for each admission to Part I., £3 3*s.*; Part II., £2 2*s.* First Professional Examination, for each admission to Part I., £4 4*s.*; Part II., £1 1*s.*; Part III. (*a*) £2 2*s.*; (*b*) £2 2*s.*; Second Professional Examination, for each admission to Part I., £2 2*s.*; Part II., £4 4*s.*

The following Regulations will apply to all candidates who pass the Preliminary Examination in General Education on or after Jan. 1st, 1923.

1. Candidates for the Licence in Dental Surgery of the Royal College of Surgeons of England are required to pass one of the Examinations in General Education recognised by the Conjoint Examining Board in England, and the Pre-Medical Examination in Chemistry and Physics conducted by that Board or one of the examinations recognised in lieu thereof, before they commence the curriculum of professional study for the Licence extending over four years.

2. Candidates who produce evidence of having been registered by the General Medical Council as Medical or Dental Students on or after Jan. 1st, 1923, will be considered to have passed the required Preliminary Examination in General Education and the Pre-Medical Examination.

3. Candidates who hold the degree of D.M.D. Harvard, D.D.S. Pennsylvania, D.D.S. Michigan, D.D.S. Illinois, D.D.S. St. Louis, Missouri, D.D.S. Northwestern University, Chicago, D.D.S. Minnesota, or the Licence of the Dental Board of Victoria, Australia, are not required to pass these Examinations.

First Professional Examination.—1. The First Professional Examination consists of Part I. Dental Mechanics, Part II. Dental Metallurgy, and Part III. Section (*a*) General Anatomy and Physiology, Section (*b*) Dental Anatomy and Physiology, and is held in January or February, April, and September or October in each year.

2. Candidates may present themselves for the several Parts of the First Professional Examination together or separately, but before admission to any part of the Examination they must produce evidence of having passed the required Preliminary Examination in General Education and the required Pre-Medical Examination or a certificate of having been registered as a Medical or Dental Student by the General Medical Council.

Part I. *Dental Mechanics.*—3. This Examination is a practical one, conducted in the Mechanical Laboratory of one of the Dental Hospitals in London.

4. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward certificates:—

(1) Of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Dental Mechanics. One year at least of this study must be taken in the Mechanical Department of a recognised Dental Hospital where the arrangements for teaching Dental Mechanics are satisfactory to the Board of Examiners in Dental Surgery. Part or the whole of the rest of the course may be taken as a pupil with a competent dentist provided that time spent as a private pupil shall be at least twice the time required for the corresponding instruction[*] taken at a Dental School.

(2) Of having attended at a recognised Dental Hospital and School: (*a*) A course of lectures on Dental Mechanics; (*b*) a course of Practical Dental Mechanics, including the manufacture and adjustment of 6 dentures and 6 crowns.

6. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having received three months further instruction under the conditions specified in Certificate (1) paragraph 4.

Part II. *Dental Metallurgy.*—7. This Examination is conducted by written paper.

8. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward a certificate:—Of having attended at a recognised Dental Hospital and School: (*a*) A course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy.

9. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having received, subsequently to the date of reference, not less than three months' instruction in Dental Metallurgy in a recognised Dental School.

---

[*] This instruction may be taken prior to the date of passing the Examination in General Education and the Pre-Medical Examination, but will not be counted as part of the required four years of professional study unless taken after passing the Pre-Medical Examination.

Part III. (*a*) *General Anatomy and Physiology*, (*b*) *Dental Anatomy and Physiology*.—10. This Examination is partly written and partly oral.

11. Candidates may enter for Section (*a*) only or for Sections (*a*) and (*b*) together on producing the required certificates, but they will not be allowed to proceed with Section (*b*) until they have passed in Section (*a*). In the case of a candidate who enters for both Sections and fails in Section (*a*) the fee paid for admission to Section (*b*) will not be forfeited, but will be credited to the candidate on readmission to examination in that Section. Candidates who enter for both Sections together may pass in Section (*a*) although failing to pass in Section (*b*).

12. Candidates must give 21 days' notice in writing of their intention to present themselves for the whole or for one Section of this examination and at the same time forward certificates :—

(1) For Part III. (*a*). Of having attended at a recognised Medical School : (*a*) Courses of instruction in Anatomy, including special demonstrations on prepared dissections during three terms ; (*b*) a course of dissections to include, if possible, the head and neck, during one term ; (*c*) courses of instruction in Physiology including General Biology, Biochemistry, and Biophysics, during three terms ; (*d*) a course of instruction in Histology.

(2) For Part III. (*b*). Of having attended at a recognised Dental School : (*a*) A course of instruction in Dental Anatomy and Physiology ; (*b*) a separate course of instruction in Dental Histology, including the preparation of Microscopical Sections.

13. A candidate referred at this examination who does not hold a registrable Dental Qualification will be required, before readmission to Section (*a*), to produce a certificate of three months' additional study of Anatomy and Physiology at a recognised Medical School, and will be required before readmission to Section (*b*) to produce a certificate of three months' additional study of Dental Anatomy and Physiology at a recognised Dental School.

14. *Exemptions*.—Candidates who have passed Section I. of the First Professional Examination of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Anatomy and Physiology for a degree, or other qualification, in Medicine or Surgery, registrable under the Medical Act of 1886, or for the degree of M.B. or M.D. of a Foreign or Colonial University recognised by the Conjoint Examining Board in England, are not required to pass Section (*a*).

Second Professional Examination.—1. The Second Professional Examination is held in February, May or June, and November in each year, and consists of : Part I., General Surgery and Pathology ; Part II., Dental Surgery and Pathology, and Practical Dental Surgery.

2. Candidates who have passed the First Professional Examination at least six months[†] previously may present themselves for Part I. only on producing the certificates mentioned in paragraph 6 of this section, or they may enter for the whole Examination at one time on producing the certificates mentioned in paragraphs 6 and 10 of this section.

3. Candidates must pass in Part I. before proceeding to Part II.

4. Candidates who enter for the whole Examination at one time may pass in Part I. although failing to pass in Part II. ; but if they fail to pass in Part I. they will not be allowed to proceed with the Practical and Oral Examinations in Part II. In such cases the fee paid for admission to Part II. will not be forfeited, but will be held over until such time as the candidate is readmitted to examination in that Part.

Part I. *General Surgery and Pathology*.—5. This Examination is partly written and partly oral.

6. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates :—

(1) Of having attended at a recognised Medical School : (*a*) A course of instruction[‡] in Surgery during two terms ; (*b*) a course of instruction in Medicine during two terms ; (*c*) a course of instruction in General Pathology (including Bacteriology) during two terms. (2) Of having acted as Surgical Dresser in the Out-patient Department of a recognised Hospital for three months. (3) Of having attended at a recognised Hospital or Hospitals, the practice of Medicine and Surgery, including clinical lectures, for 12 months. (4) Of being 21 years of age.

7. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of such additional study during three months at a recognised Medical School and Hospital as the Teachers of the School may determine.

Exemptions.—8. Candidates who are Members of the College or who have passed the Examination in Surgery of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Surgery for a Degree, or other Qualification in Medicine or Surgery registrable under the Medical Act of 1886, are not required to pass Part I. of the Second Professional Examination.

Part II. *Dental Surgery and Pathology*.—This Examination is partly written, partly oral, and partly practical. The oral examination is conducted by the use of preparations, casts, drawings, &c. At the practical examination candidates may be examined :—

(*a*) On the treatment of Dental Caries, on the preparation and treatment of teeth by filling with gold or other material, by inlaying or by crowning, and on other operations in Dental Surgery. (Candidates must provide their own instruments.) (*b*) On the treatment of abnormalities of position of the teeth of children. (*c*) On Clinical cases.

10. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates :—

(1) Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a Medical or Dental Student, or of having passed the Pre-Medical Examination conducted or recognised by the Conjoint Examining Board in England. (2) Of having attended at a recognised Dental Hospital and School : (*a*) A course of Dental Surgery and Pathology ; (*b*) a separate course of Practical Dental Surgery ; (*c*) a course of Dental Bacteriology ; (*d*) a course of Dental Materia Medica ; (*e*) a course of practical instruction in the administration of such Anæsthetics as are in common use in Dental Surgery. (3) Of having attended at a recognised Dental Hospital and School, or in the Dental Department of recognised General Hospital, the practice of Dental Surgery during two years.

11. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required before admission to re-examination to produce a certificate of three months' additional study at a recognised Dental Hospital.

Fees.—The fee for the Diploma in Dental Surgery is 20 Guineas.

Synopses of examinations and all further information can be obtained from the Secretary, Examination Hall, Queen-square, London, W.C. 1.

Royal College of Surgeons, Edinburgh.—Regulations giving a list of Preliminary Examinations recognised for obtaining the Licence in Dental Surgery, as well as of the subjects of the Professional Examinations, may be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, at 49, Lauriston-place, Edinburgh. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates must also have attended a course of instruction at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the Diploma in Surgery. In addition they will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, special courses of lectures and instruction in Anatomy and Physiology (Human and Comparative), Surgery, Pathology, Materia Medica, Dental Histology, and Practical Dental

---

[†] The interval of six months is not required in the case of a colonial or foreign dentist.

[‡] These courses of instruction must be attended after the completion of the courses in Anatomy and Physiology.

Mechanics and Metallurgy; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised Dental Hospital and School, for three years. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the required courses. The examination embraces (1) Chemistry and Physics; and (2) Anatomy and Physiology. The fee is £5 5*s.* for the complete examination, and £3 3*s.* is payable for each division. In all cases of rejected candidates the fee for re-entry is £3 3*s.* Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10*s.*, for re-entry £5 5*s.* The examination embraces (1) Surgery and Medicine; and (2) the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Materia Medica, Dental Mechanics and Dental Metallurgy, with a practical as well as the written and oral examinations in the subjects of Dental and Oral Surgery, Pathology, and Mechanics. The candidate will be tested in the Treatment of Dental Diseases, in Operative Dentistry, the Administration of Anæsthetics, Orthodontics, and in Prosthetic and Mechanical Dentistry. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations or other recognised examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15*s.* payable for the dental diploma. Candidates applying for copies of Regulations should state date of registration as a dental student. Fees and schedules must be lodged with the Clerk not later than one week before the examination.

Higher Dental Diploma.—The College grants a Higher Dental Diploma which is registrable in the Dentists Register as an additional qualification. Every candidate for the Higher Dental Diploma shall produce evidence that he has been engaged in the study or practice of his profession as a Registered Dentist for at least one year subsequent to his having obtained the Licence in Dental Surgery of the College, or a Licence or Qualification in Dental Surgery specially recognised by the College. Particulars as to the examinations can be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, 49, Lauriston-place, Edinburgh. The fee payable by Licentiates of the College is £15 15*s.* For all other candidates £21. A fee of £10 10*s.* is retained for examination expenses in the case of referred candidates.

The examination embraces the following branches of Dental Science and practice: Dental Surgery, Anatomy, Pathology and Bacteriology, Prosthesis, Anæsthesia, and Dental Radiology. The examination will be clinical and practical as well as written and oral. Candidates will be expected to show a high degree of knowledge and skill.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bacteriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Candidates for the Licence in Dental Surgery, aged at least 21, pass two professional examinations. Before the First Examination the candidate must produce evidence of having attended courses in Theoretical and Practical Chemistry, including Metallurgy and Physics, at a recognised institution; of having been registered as a medical or dental student by the General Medical Council; and of having attended courses of instruction in the following subjects at a recognised school of medicine: (*a*) Anatomy Lectures; (*b*) Dissections with Demonstrations; (*c*) Physiology, including Dental Physiology; (*d*) Practical Physiology and Histology, including Dental Physiology and Histology, Human and Comparative. Before the Final Dental Examination the candidate must have been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the Mechanical Department of a recognised Dental Hospital, and have attended, at institutions recognised by the College for the purpose, the following courses of instruction: (*a*) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (*b*) Dental Mechanics. Lectures. Two courses. (*c*) Dental Anatomy. Lectures. One course. (*d*) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Two years. He must also have attended Clinical instructions at a recognised General Hospital during the ordinary teaching sessions (nine months), and have been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student. One year's bona-fide apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. In the First Dental Examination candidates will be examined in (A) Physics and Chemistry, including Practical Chemistry and Metallurgy. (B) Anatomy, Physiology, and Histology—General and Dental. All the subjects may be passed at the same time, or they may be passed in two groups (A and B).

In the Final Dental Examination candidates will be examined in General Pathology, Medicine, and Surgery; Dental Surgery, and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery; Dental Mechanics and Metallurgy; Orthodontia. Candidates must pass in all the subjects at one examination. The total fee for the Diploma in Dental Surgery is 20 guineas.

UNIVERSITY OF BIRMINGHAM.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum: The "John Humphreys Odontological Museum." An Entrance Exhibition, value £37 10*s.*, is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—

1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees.

3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A*. In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Elementary Biology and Organic Chemistry, (*b*) Anatomy and Practical Anatomy, and (*c*) Physiology and Practical Physiology. *B*. That he has passed the class examinations in: (*d*) One Special Course of Lectures on Medicine, (*e*) One Special Course of Lectures on Surgery, and (*f*) Pathology and Bacteriology. *C*. That he has attended courses and passed the class examinations in: (*g*) Dental Histology and Patho-Histology, (*h*) Comparative Dental Anatomy, and (*k*) Dental Surgery and Prosthetic Dentistry. *D*. That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D*. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work, and investigations in some subject connected with Dentistry, which theses shall be submitted to examiners to be nominated by the Dental Advisory Board.

UNIVERSITY OF BRISTOL.—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than five years, of which three shall have been passed in the University, and shall have been registered as dental students by the General Medical Council. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Biology, and the curriculum extends over one year.[*] The Third Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for three years an approved pupilage in Dental Mechanics. The Second Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall have passed an entrance examination satisfactory to the University before being admitted to any professional examination; the curriculum extends over four years from the date of passing a preliminary science examination in Chemistry and Physics. A three years' pupilage in Mechanical Dentistry is required[†] and four examinations must be passed, the subjects of which agree with those of the B.D.S. Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

UNIVERSITY OF DURHAM.—Every Dental student must, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for Medical students.

First Examination: This examination consists of two parts, which may be passed separately. Part 1, Biology, Organic Chemistry. Part 2, Theoretical Dental Mechanics, Dental Metallurgy (theoretical and practical). Second Examination: Anatomy, Physiology (including biochemistry and biophysics), Dental Anatomy and Dental Histology. Third Examination: Pathology and Bacteriology, Practical Dental Mechanics, Dental Materia Medica and Therapeutics. Final Examination: Medicine, Surgery, Dental Surgery and Pathology, Orthodontia, Operative Dental Surgery, and Dental Prosthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the following subjects, attended after registration as a dental student at recognised Colleges or Schools: (*a*) Organic Chemistry; (*b*) Elementary Biology[*]; (*c*) Human Anatomy, with dissections and demonstrations for three academic terms; (*d*) Physiology, including Biochemistry and Biophysics (with laboratory instruction, including practical Histology) for three academic terms; (*e*) General Pathology (including Bacteriology) for two academic terms; (*f*) Medicine for two academic terms; (*g*) Surgery for two academic terms; (*h*) the practice of a recognised General Hospital or Hospitals of not less than 80 beds, with certified instruction in Clinical Medicine and Clinical Surgery, for four academic terms. The certificates of teaching at General Hospitals must furnish evidence of the student having acted as Medical Clinical Clerk and Surgical Dresser, and of attendance in the Out-patient or Casualty Departments. A certificate of clinical instruction in Venereal Disease is required.

The candidate must have attended at a recognised Dental School courses of instruction in the following special subjects: (*a*) Dental Anatomy and Physiology, human and comparative. The course should comprise a minimum of 20 meetings of the class. (*b*) Practical Dental Histology and Morbid Histology. The course should comprise a minimum of 16 meetings of the class. (*c*) Dental Pathology and Surgery. The course should comprise a minimum of 20 meetings of the class. (*d*) Dental Materia Medica and Therapeutics. The course should comprise a minimum of 16 meetings of the class. (*e*) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of 20 meetings of the class. (*f*) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of 20 meetings and 20 demonstrations. (*g*) A course of instruction in the use of Anæsthetics, general and local, employed in Dental Practice. (*h*) A course of instruction in Radiology as applied to Dentistry.

Note.—A candidate must produce a certificate of having administered general anæsthetics on at least ten occasions.

The candidate must have for at least 24 calendar months attended, during the ordinary academic terms, the practice of a recognised Dental Hospital or of the recognised Dental Department of a General Hospital, and have received for not less than 24 calendar months practical instruction in Dental Mechanics.

Note.—No portion of such practical instruction which is taken prior to the date of registration shall be reckoned as a portion of the four years of Professional Study required.

Instruction in Dental Mechanics should, if possible, be taken at a recognised Dental Hospital and School. If any part of such instruction be taken by the candidate as a pupil with a registered dentist the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a Dental Hospital and School.

---

[*] Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

[†] This pupilage must be taken either in the University laboratories or those of some institution recognised for the purpose by the University.

[*] A student who has diligently attended an approved course of Elementary Biology in a secondary school or other teaching institution recognised by the University may be admitted to a Professional Examination in Elementary Biology immediately after his registration as a dental student.

The examinations will be held concurrently with the medical examinations, and the fees payable by candidates are as follows: First Examination, £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £3 10*s.*; Final Examination, £3 10*s.*; fee for Licence, £3; total, £15. For re-examination: First Examination, £1 10*s.*; Second Examination, £2; Third Examination, £2 (in one part only, £1); Fourth Examination, £2. The practical examinations in dentistry will be conducted at the Newcastle Dental Hospital.

University of Leeds.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the First Examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. The classes in the Department of Dentistry begin on Oct. 1st. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology are given at the University in College-road. The classes in the other subjects and the systematic courses in Dental subjects are held in the School of Medicine of the University in Thoresby-place. The clinical instruction is given in the Dental Department at the Leeds General Infirmary. Applications for the prospectus should be made to the Dean of the Faculty of Medicine.

University of Liverpool.—The University grants a Licence in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The management of the curriculum (lectures, practical and clinical) is in the hands of the University Board of Dental Studies. The courses of systematic instruction are given in the main University buildings, and those in Dental Mechanics, Operative Dental Surgery, &c., are given in the University School Extension (opened 1922), adjoining the Dental Hospital, the laboratory of which is in charge of a skilled dental mechanic under the supervision of the Director of Dental Education. The clinical instruction is given in the Dental Hospital. Students can take the whole curriculum including Dental Mechanics, at the University School of Dental Surgery. The times of the lectures at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. Fees: The fees for the complete courses, including Pupilage and Hospital Practice, are as follows: Degree of B.D.S., £237 10*s.*; M.D.S., £20; L.D.S. (Liverpool), £199; L.D.S. (other licensing bodies), £203. Further information may be had from the Director of Dental Education, Prof. W. H. Gilmour.

In order to be admitted to the Bachelor's Degree in Dental Surgery a student must normally, after registration as an Internal Student, have—(1) Attended prescribed courses of study for five years at one or more Schools of the University. (2) Passed the following examinations: (*a*) First Examination (Part I., Chemistry, Physics; Part II., Zoology); Second Examination (Part I., Dental Metallurgy; Part II., Dental Mechanics); Third Examination (Part (*a*) Physiology and Histology, and Dental Anatomy and Dental Histology, Part (*b*) Anatomy and Dental Materia Medica and Therapeutics); Final Examination (Medicine, Surgery, Dental Surgery, Clinical Dental Surgery and Prosthetic Dental Surgery, Dental Pathology and Dental Bacteriology). Students who have received not less than two years' instruction in Dental Mechanics previous to Nov. 30th, 1922, with a Dentist registered under the provisions of the Dentists Act (1921) and who have passed a recognised examination in Preliminary education may, on application, be registered as students for the Licence under certain conditions.

University of London.—The curriculum for the degree of Bachelor of Dental Surgery covers five years from Matriculation. The Regulations for Internal and External Students may be obtained post-free on application to the Principal Officer, at the University.

University of Manchester.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given throughout the session both at the University and at the Dental Hospital of Manchester adjoining the University. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department, and for them common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 93 guineas, payable in three equal yearly instalments. The composition fee for candidates for the University Diploma in Dentistry is 83 guineas, payable in three equal yearly instalments. The composition fee for candidates for the L.D.S. of England is 93 guineas, payable in three equal yearly instalments. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The composition fee does not include the hospital fees, the examination fees, nor the fee for the conferment of the degree or the diploma.

University of Sheffield: *Degree of Bachelor of Dental Surgery.*—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five and a half years subsequent to matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year after matriculation and the passing of the further examination in Chemistry and Physics. Second Examination: The subjects of the examination are Anatomy, Physiology, Dental Anatomy, Physiology and Histology; Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are Part I., General Pathology and Bacteriology, Dental Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed five and a half years of professional study.

Degree of Master of Dental Surgery.—Candidates must have passed the examination for the degree of B.D.S. at least one year previously and before admission to the examination must have held for not less than six months a dental appointment in a hospital affording full opportunity for the study of Dental Surgery. Candidates shall not be required to but may present a thesis embodying observations in some subject approved by the Faculty and a candidate whose thesis is of exceptional merit may be exempted from any part of the examination.

Diploma of Licentiate in Dental Surgery.—A candidate must have attained the age of 21 years on the day upon which he is to receive the diploma, and have pursued the courses of study required by the University regulations during a period of not less than four years subsequently to matriculation and the passing of the further examination in Chemistry and Physics. Two years must be passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year. Second Examination: The subjects of the examination are Anatomy and Physiology, Dental Anatomy and Physiology, Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., General Pathology and Bacteriology; Dental Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed the fourth year of professional study.

The Dental Composition Fee is £25 for each year of the course. In addition a fee of £50 is payable each year the student receives instruction in Mechanical Dentistry in the Dental Department.

National University of Ireland.—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

Queen's University of Belfast.—At the beginning of session 1920–21 a Department of Dentistry was opened, and the following degrees and diplomas are now conferred: Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery. Lecturers have been appointed in Dental Surgery, Dental Mechanics, Dental Metallurgy and Materia Medica, and Orthodontia.

Teaching Institutions in Dentistry.

In addition to facilities provided by the above Universities a number of other dental courses are available. In London, at the Royal Dental Hospital (School of Dental Surgery), Leicester-square, at University College Hospital Dental School, and at the dental departments of Guy's Hospital and of the London Hospital. In the Provinces, at the Birmingham, Manchester, and Newcastle-upon-Tyne Dental Hospitals. In Scotland, at the Incorporated Edinburgh Dental Hospital, the Incorporated Glasgow Dental Hospital, and the dental department of Glasgow Royal Infirmary. In Ireland, at the Incorporated Dental Hospital of Ireland, Dublin.

Medical News.

Westminster Hospital.—The annual old students' dinner will be held on Thursday, Oct. 4th, at the Empire Rooms, Trocadero Restaurant, Piccadilly, Mr. W. G. Spencer in the chair. The hon. secretary is Dr. Adolphe Abrahams, 17, Harley-street, W. 1.

Small-pox in England and Wales.—The number of cases reported during the week ending August 11th was 28. Of these, 20 were from Gloucestershire, 4 from Notts, 3 from Yorks (West Riding), and 1 from Derbyshire.

Lancashire and the Spahlinger Treatment.—In view of the refusal of the Health Ministry to allow part of the accumulated funds of approved societies to be used in obtaining this treatment for insured persons, it has been decided that a party of representatives of some societies pay a visit to Switzerland in September to make investigations on the spot.

Sleep in Churches.—The Bishop of Durham, writing in his *Diocesan Gazette*, appeals for more ventilation in churches, and states that in his opinion the ventilation of parish churches tells more directly on the efficiency of the ministrations of the clergy than many other circumstances apparently more relevant, whilst inattention and restlessness on the part of the congregations result from the breathing of a thoroughly vitiated atmosphere.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, August 27th.—10 a.m., Mr. Maingot: Surgical Pathology. 12 noon: Mr. Simmonds: Applied Anatomy. 2 p.m., Mr. Addison: Surgical Wards.

Tuesday.—12 noon, Dr. Burrell: Chest Cases. 2 p.m., Mr. Sinclair: Surgical Out-patients. 2.30 p.m., Dr. Pritchard: Medical Wards.

Wednesday.—12 noon, Mr. Sinclair: Abdominal Surgery. 2 p.m., Mr. Gibb: Eye Dept. 3 p.m., Dr. Pernet: Skin Dept.

Thursday.—12 noon, Mr. Simmonds: Demonstration of Fractures. 2 p.m., Mr. MacDonald: Genito-Urinary Dept. 3 p.m., Dr. Scott Pinchin: Medical Out-patients.

Friday.—10 a.m., Mr. Dudley Buxton: Dental Dept. 2 p.m., Dr. Burrell: Medical Out-patients. 2 p.m., Mr. Banks-Davis: Nose, Throat, and Ear Dept.

Saturday.—Dr. Paterson: Diseases of Children (Medical).

Daily, 10 a.m. to 6 p.m. Saturdays, 10 a.m. to 1 p.m. In-patients, Out-patients, Operations, Special Departments.

Births, Marriages, and Deaths.

BIRTHS.

Carlill.—On August 15th, at North Gate, Regent's Park, Mildred (née Godfrey), wife of Hildred Carlill, M.D., of Harley-street—a daughter.

Gauntlett.—On August 17th, at 18, Walker-street, Edinburgh, to Hilda Mary (née Gerrard), wife of Eric Gerald Gauntlett, C.B.E., D.S.O., F.R.C.S., of Shanghai—a son.

MARRIAGES.

Geldart—Dixon.—On August 14th, at Holy Trinity, Loddon, Norfolk, Richard Morton Geldart, M.A. Camb., M.R.C.S., L.R.C.P., of Worthing, Sussex, to Margaret Lucy, youngest daughter of Rev. and Mrs. Dixon, of Loddon Vicarage, Norfolk.

JOHN BALE, SONS & DANIELSSON, LTD., 83-91, Great Titchfield St., Oxford St., W.1.

The epithelial lining of the mammary gland consists throughout of one layer of epithelial cells, beneath which is a layer of smaller, more or less flattened, supporting cells. In the main ducts the cells of the glandular layer are columnar or cylindrical in shape, and these give way, as the ducts branch, to cells which are more definitely cubical. The transition from columnar to cubical is not abrupt but very gradual, and it is difficult, or impossible, to say where duct ends and acinus, or true secretory tissue, begins. The truth is, I believe, that all the cells participate in the secretion, and the difference lies rather in the chemical composition of the secretion than in their morphology. Even in the immature breast, which contains only the large collecting ducts, these ducts are filled with a fluid secretion.

Several modifications in shape are seen in a duct as it passes from the surface of the nipple to the interior of the breast. These changes appear to me to be of great, though imperfectly appreciated, importance in the pathology of the diseases of the breast. I wish to draw particular attention to the manner in which the ducts open on the surface of the nipple. In the accompanying drawing (Fig. 1 on Plate) it will be seen that the actual mouth of the duct is a funnel-shaped structure lined with ordinary squamous epithelium. These squamous cells extend for a considerable distance below the surface of the nipple, and in the inactive breast the point at which they end—that is, at the neck of the funnel—the lumen of the duct becomes extremely narrow and is usually almost obliterated. Immediately beyond this point there is an abrupt transition from squamous to columnar epithelium, and at the same time the duct suddenly opens out, the lumen becoming wider than at any other part of its course. This part forms the ampulla of anatomical nomenclature. The walls of the ampulla, unless it be greatly distended with secretion, are irregularly folded, and so it can adapt itself to wide variations in content.

A further point which I wish to emphasise is the fact that the funnel-shaped mouth of the duct is lined with an epithelium which normally keratinises on the surface. These keratinised layers inevitably tend to accumulate in the depression formed by the funnel, and I have found that in the non-lactating breast the mouths of the ducts are, almost without exception, filled by a laminated plug of keratinised epithelium. I have examined a very large number of nipples, both by making longitudinal sections and by serial transverse sections. In a longitudinal section the plug can be seen to form a cone-shaped cast of the mouth of the duct. In a transverse section (Fig. 2 on Plate) the laminated plug is well seen. As soon as the narrow neck of the funnel has been passed the plug disappears and the duct opens out again, as has already been said. The mouth of the duct in a lactating breast forms a striking contrast to this. The narrow neck is now widely open, and the epithelial plug, except for a few layers at the periphery, has disappeared. Sections of the nipple also show the large amount of unstriped muscle tissue, disposed rather irregularly in small bundles, which this structure contains. The contraction of this muscle is presumably largely responsible for the narrow neck of the funnel. In any case it is clear that no secretion present in the ampullæ of a non-lactating breast is normally allowed to escape. The duct therefore becomes additionally sealed by a firm epithelial plug. This may be accentuated by the retraction or deformity of the nipples which is often found to be associated with chronic mastitis, and is by no means to be regarded as a sign diagnostic of carcinoma.

Normal Physiology of the Breast.

It may seem at first somewhat superfluous to devote a special section of a paper on the pathology of an organ to a consideration of its normal physiology; but in the case of the breast I believe the latter to be to a large extent the key to its pathology. I have hitherto spoken of the breast as a gland either inactive or functioning—that is, lactating; but I now wish to put forward the view that the breast is a gland which throughout life is exhibiting some secretory activity, the difference between a lactating and a non-lactating breast being one partly of degree and partly of the chemical constitution of the secretion.

The physiological history of the mammary gland begins at birth, when there is often an abortive attempt to fulfil its ultimate function of lactation. This may be called clinically an "infancy mastitis," and is presumably to be explained by the fact that both fœtal and maternal breasts are subjected to the same hormonic stimulus. I have no knowledge of the histological appearance in such a case, but I do know that in many of the sections of breasts of young children that I have seen, the ducts are considerably distended with secretion, which may be taken as evidence that the cells of the immature gland have some functional activity. The clinical condition of mastitis is not, however, often seen in children between infancy and the age of 11 or 12, but from this time onwards the physiology of the breast is very intimately connected with that of the sexual glands. After the age of 11 in girls and 13 in boys the condition of "puberty mastitis" is very commonly seen. There is a painful swelling of one or both breasts, which, though not acute, may persist in boys for two or three years and then disappear. In girls it passes into the phase of normal hypertrophy which attends the attainment of sexual maturity.

In girls, with the arrival of sexual maturity the mammary glands enter upon a phase of permanent semi-activity, and are subjected to a constantly recurring physiological stimulation which is repeated in varying degrees at frequent intervals for a period of at least 36 years. At every menstrual period the glands are acted upon by hormones from the sexual glands, which awaken some sort of activity in the epithelial cells. In many women this may pass unnoticed. Many others are painfully conscious of the process and may be led to consult a doctor about it, who will perhaps make a diagnosis of "chronic mastitis." The condition should perhaps rather be called at first "menstrual mastitis," though as time goes on the physiological state becomes more and more difficult to distinguish from the pathological. In the event of pregnancy becoming established, the menstrual cycle is for the time being abolished, and a different form of hormonic stimulation is substituted. In response to this the cells enter upon their full functional activity, and a period of enormous hypertrophy, culminating in lactation, follows. Lactation is succeeded by a process of shrinkage, during which the cells of the hyperplastic gland largely disappear and are absorbed—unless further pregnancies follow in quick succession, in which case the gland may be almost continuously active for several years.

At about the age of 48 the possibility of further pregnancies comes to an end, but the phase of the climacteric may subject the mammary glands to a series of irregular hormonic stimuli, which only cease with the final establishment of the menopause. Then, and then only, are these glands allowed to rest, and I believe that in strict normality an almost complete atrophy of glandular tissue gradually takes place. First the acini disappear, then the small ducts, and finally only the largest collecting ducts remain. Even in these the cells are small, and the lumen greatly shrunken. The connective-tissue framework may also become reduced in bulk, though the external appearance of the breast would often belie this owing to its becoming infiltrated with fat. After the menopause, therefore, and in old age, there is no true physiology of the breast to record, but too often a physiological process has become merged in a pathological condition, which probably has had its origin many years before. A physiological stimulus may amount to a pathological insult if only it is repeated often enough. It may be asked why I have chosen to dwell in such detail upon a series of physiological commonplaces. My object has been to emphasise the fact that the epithelial cells of the breast are producing some sort of secretion almost continuously for many years. I have already demonstrated that, except during lactation, the mouths of the ducts are not normally patent, and that no secretion can escape. The physiology of the breast entails, therefore, not merely secretory, but also continuous absorptive, activity. I shall return later to the bearing of this upon the pathology of chronic mastitis.

HISTOLOGICAL EVIDENCE OF MASTITIS.

I now turn to a description of the histological changes which I believe to be indicative of the presence of chronic mastitis. I can but describe each one in turn; it must be understood, however, that all may be seen at once in one small area, though as a rule their relative distribution in the breast is very erratic. If, as the name of the disease implies, it is an inflammatory condition, then it would be expected that one of the cardinal signs of inflammation, infiltration of the connective tissues with leucocytes, would invariably be present. Actually, the presence of round cells is not an invariable sign, or, at any rate, all parts of the diseased breast are not equally affected.

It is, however, evident that the round-celled reaction is more intense when the lumen of the acini or ducts that they surround is filled with a fluid rich in disintegrating cells or fat-containing secretion. The mere presence of epithelial changes certainly does not on the whole tend to determine a concentration of leucocytes. It is the presence of dead cells or inspissated secretion which attracts them most strongly. The microscopic appearances suggesting *inflammation* are therefore indirectly produced by interference with the escape of the products of epithelial activity from ducts and acini. The most extreme condition of leucocytic infiltration that I have found was in the breast of a woman who became pregnant after having developed an advanced chronic mastitis. The breast attempted to lactate, but the secretion was unable to escape normally, and re-absorption of the milk was only effected with an intense inflammatory reaction. A similar condition, which may be called a "stagnation mastitis," is seen clinically in a woman who has for some reason been compelled to cease suckling her child soon after its birth. Re-absorption of secretion is then attended by acute pain and inflammation, which may initiate a chronic mastitis and give rise to considerable suffering in a subsequent pregnancy. It is important to note what type of cell is most commonly found, and it is clear that the lymphocyte nearly always predominates. In the extreme case mentioned there were also a good many polymorphonuclear cells, and in another there were large numbers of eosinophil cells producing a very unusual appearance.

The presence of fibrosis is another change seen in the interstitial tissues which is very capricious in its distribution. Often the first evidence of true fibrosis is seen as an increase in the density of the layer of fibrous cells immediately outside the ducts or acini. In sections stained with eosin this is seen as a conspicuous red rim round these structures, consisting of several layers of connective-tissue cells. In another form of fibrosis the area of loose and transparent connective tissue round the groups of acini tends to become contracted or to disappear altogether. The eosin staining then extends evenly right up to the acini. In a later stage the epithelial cells may disappear and be replaced entirely by fibrous tissue arranged as a group of small whorls, each whorl presumably representing an acinus. This appearance tends to resemble the arrangement of fibrous tissue seen in a fibro-adenoma intracanaliculare, and that, after all, is probably the late stage of an originally glandular tumour in which the fibrous tissue has become predominant at the expense of the epithelial cells.

Dilatation of ducts and acini is a change that almost always accompanies chronic mastitis, but it is difficult to judge at what point the process is to be regarded as pathological. For it is quite normal to find a dilatation of the large collecting ducts and ampullæ which can be seen with the naked eye when the breast is sliced, and this is only to be expected in a secreting gland which has no outlet except when lactating. As the secretion accumulates, this distension may be communicated to the smaller ducts and finally to the acini, which normally have only a very small lumen; but clearly there is no criterion indicating definitely the point at which the process becomes pathological. I have therefore not been able to use any particular standard. Each section has been judged on its merits. The formation of small cysts which can be felt with the fingers is characteristic of chronic mastitis, but this is only a more advanced stage of a change which can at first only be appreciated under the microscope. The presence of large cysts lined by flattened epithelium and filled with a clear greenish fluid, a turbid milky fluid, or a cheesy mass is also characteristic of a still later stage of mastitis. These advanced changes are presumably associated with obstruction to a duct by fibrosis, cellular proliferation, or pressure; but I have not been able to demonstrate this in relation to any particular cyst.

The epithelial changes in chronic mastitis are more definite and more easily identified than those described so far. The changes appear to me to be of two different types. In one type the change is primarily an enlargement or swelling of the cells without very much active proliferation; in the other the cells do not always undergo any alteration in size, but simply proliferate in varying degrees, forming either the "laciform proliferation," so named by Sir Lenthal Cheatle, or "massive proliferation," solid lumps or columns of cells filling and distending the spaces originally occupied by the acini or ducts in which the process arises. The first change may be partly degenerative, but it is not connected with the so-called "involution changes" seen in the breasts of women who have passed the menopause, for I have found it at all ages from 16 upwards. Nor do the cells show any fatty changes in their cytoplasm when tested with the special fat stains. It seems, on the other hand, to be associated with some form of irritation, and may occur in patches (Fig. 3 on Plate). In most instances the change seems to spread and involve the glandular tissue of neighbouring groups.

The second type of cellular change is, as I have said, primarily a proliferative change, and clearly indicates a much greater activity in the cells. Often, as proliferation proceeds, some of the cells are cast off and disintegrate. When these have disappeared a "laciform" appearance will presumably result. This is not in any essential particular different from the massive proliferation seen in Fig. 4 (on Plate), where the outlines of a few acini can still be made out.

Another change which seems to be closely associated with the cellular changes already described takes place chiefly in the larger ducts, and results in the formation of true papillomata. The first stage of this is shown in Fig. 5 (on Plate), where the wall of a distended duct is seen to be sprouting small excrescences all round its circumference. Such papillomata are commonly found in the ducts close to the nipple and their presence often gives rise to a clear or blood-stained discharge from the nipple, and this usually attracts the patient's attention. But I do not believe that such a papilloma ever occurs as an isolated phenomenon. The signs of chronic mastitis would certainly be found in other parts of the breast if search were made for it.

Summarised in as few words as possible the histological changes seen in chronic mastitis are: round-celled infiltration, fibrosis, dilatation, epithelial changes of two kinds, and formation of papillomata. In the early stages of the disease some degree of fibrosis, as described here, some degree of dilatation of the small ducts or acini, and a few patches of round cells are the chief histological evidences of its presence. In the later stages all these changes become accentuated and are associated with one or both of the forms of epithelial change. Sometimes the leucocytic activity appears not to be accentuated at this stage, but may, on the other hand, be almost absent. In the stage at which operation is performed the slight dilatation has usually culminated in the formation of large cysts, but at this point the condition is given a number of different names indicating supposedly distinct diseases. The laciform or massive proliferation clearly indicates that a profoundly abnormal activity has been somehow induced in the epithelial cells, and this may be of the greatest importance in considering the question of malignancy. This will be discussed later.

Age- and Sex-Incidence of Pathological Changes in the Breast.

One object of this investigation was to ascertain, if possible, at about what age the changes of chronic mastitis first become apparent. It is difficult, however, to obtain accurate facts from statistics based on the relatively small numbers to which I was necessarily limited. The post-mortem room material provided 116 specimens, of which 57 were normal and 59 showed inflammatory lesions. In the accompanying chart is shown the percentage, in every decade, of individuals having positive signs of chronic mastitis. It will be seen that the lesions first become apparent in the second decade, and rise to a maximum in women aged 40 to 50. It is, of course, possible that the figure of 18 per cent. in the second decade would be lower if I had more material on which to base it. Also I feel quite sure that the extreme irregularities seen in the graph after the age of 60 are quite misleading, the number of cases beyond this age that were investigated being very small. I have therefore shown this part only in dotted lines. It is evident from this diagram that chronic mastitis is not a disease of the climacteric only, as has sometimes been supposed. It may have had its beginnings 30 years before this, though it is most apt to become clinically obvious at the later age.

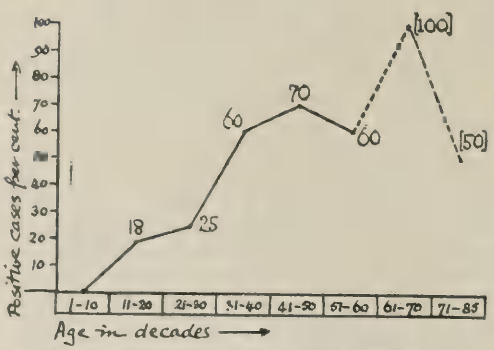

Chart showing percentage in every decade of persons having positive signs of chronic mastitis.

Post-mortem room material also gives some indication of the influence of lactation upon the incidence of chronic mastitis. Details of family history had not been recorded in all cases, but the figures as far as they could be ascertained were as follows:—

Post-Mortem Room Material.

Average age of all positive cases	unmarried or childless ..	43 years.
	parous women	51 ,,

A similar impression is obtained from the series of cases which had developed manifestations of mastitis necessitating operation. The youngest unmarried patient in this series was 24. The youngest married patient was 46. The average ages were as follows:—

Operation Material.

Average age of unmarried patients.. ..	37 years.
,, ,, married patients	46 ,,

It seems to be clear that chronic mastitis tends to appear nearly *ten years* earlier in single women than in those who have borne children.

I have so far referred only to the incidence of chronic mastitis in the female sex. It is well known, however, that males may suffer from all the same affections of the mammary glands as females, though very much less commonly. The early physiological types of inflammation in the breast—namely, infancy and puberty mastitis—occur almost as often in boys as in girls. Afterwards the breast in the male becomes quiescent. In later life, however, men may develop in their breasts all the same conditions as are seen in women. Ordinary chronic mastitis is not very rare in old men. Sometimes cysts, papillomata, and so forth are developed, and may necessitate operation. A definite percentage of cases of carcinoma of the breast is found in men. I thought it worth while, therefore, to examine a series of male breasts from the post-mortem room, in order to find out how often the changes of chronic mastitis were to be found. I have examined 37 specimens, and found some changes in four of them. In one of these, from a man of 38, the picture was that of a well-developed chronic mastitis. Some of the ducts were enormously dilated, and the secretion contained large numbers of cells. In some places there was swelling and desquamation of the epithelial cells, and there were numerous patches of round-celled infiltration. The average age of the four patients was 54. It was noticeable that almost every specimen showed that the ducts had a wide lumen and contained secretion, so that the conditions very closely resemble those found in women. It must be remembered, however, that the gland tissue in the male is represented only by the largest collecting ducts. In the female breast the changes of mastitis are seldom seen in these large ducts, but are almost always in the smaller ducts or acini, which do not exist in the male. It may be, therefore, that the epithelium of the large ducts is for some reason less vulnerable, and so less liable to pathological changes, than that of the more truly glandular tissue. Perhaps it is partly to this that the male breast owes its comparative immunity from disease. It is also less subject to irregular hormonic stimuli.

Theories of Causation.

As indicated at the beginning of this paper, the idea of the causation of chronic mastitis that has commonly held the field is one involving the presence of some obscure bacterial infection. I cannot, however, discover any evidence in favour of the view that the inflammation is bacterial. All that I can gather seems to show that bacteria take no share in the disease.

I have shown, I believe conclusively, that the normal breast has, except during lactation, no outlet through the nipple. The mouths of the ducts are mechanically closed a little way below the surface by muscular contraction which reduces the lumen almost to nothing. They are in addition sealed by a firm plug of epithelium, reinforced by sebaceous secretion, a substance which is known to be unfavourable to the growth of bacteria. It seems very unlikely, therefore, that any foreign substance could obtain entrance through the nipple. It cannot be claimed that lactation affords an opportunity for infection from without, since the changes of chronic mastitis are so often found in breasts which have never lactated. There is the alternative supposition that bacteria may have been brought to the breast by the blood-stream. In the case of a tuberculous infection this undoubtedly happens, and presumably a pyogenic infection may occasionally occur in the breast in the course of a blood infection, as may happen in any other part of the body; but it is difficult to believe that every one of the vast number of women afflicted with chronic mastitis has pyogenic bacteria circulating in her blood in numbers large enough to produce a diffuse lesion in both breasts.

In either case it should be possible to recover these bacteria from a breast showing a well-marked degree of mastitis; but this I have invariably failed to do. Also the histological appearances do not suggest the presence of bacteria. Bacterial infection is almost invariably accompanied by a leucocytic reaction. This, as has been said, is often absent in chronic mastitis. Also the leucocyte characteristic of pyogenic infection is the polymorphonuclear cell. In chronic mastitis it is always the lymphocyte which is present, almost to the exclusion of polymorphonuclear leucocytes. Nothing can be inferred from the presence in one case of large numbers of eosinophil leucocytes.

I have mentioned that enlargement of the axillary lymph glands is often associated with chronic mastitis, but this cannot be interpreted as necessarily indicating bacterial infection. Absorption of any toxic products, bacterial or non-bacterial, may produce signs of lymphadenitis in the glands draining the affected area. It seems reasonable, therefore, to reject the bacterial theory of causation on the ground that there is no evidence to support it. Another theory which has been advanced suggests that chronic mastitis may be caused by a general toxæmia, the source of the toxin being a site of bacterial activity in some part of the body. Thus it was observed by C. B. Lockwood[1] many years ago that the symptoms of an inflammatory tumour in the breast disappeared after the removal of a source of infection, such as an infective vaginitis. More recently, affections of the mammary gland have been connected with intestinal toxæmia by W. S. Bainbridge.[2] But judgment as to the possible connexion between chronic mastitis and chronic toxæmia must be suspended until more precise evidence than is given by these authors is forthcoming. Another condition which has been held by many writers to be responsible for chronic mastitis is one that is termed "involution change"; but after lactation this change is probably passive in most respects, and according to the most recent view[3] results partly from a lessened blood-supply, and partly from the pressure produced by the secretion which is no longer removed as it is formed. This effect may be aided by bandaging. Under these conditions the epithelial cells undergo autolysis or self-digestion, the products of this metabolism being then removed by way of the lymph- or blood-stream. In this way the hypertrophied organ is removed piecemeal in a relatively short time, until nothing but the ducts with their normal proportion of branches and acini remain. It is difficult to see how any abnormal cellular processes could be initiated in this manner. It is often stated also that involution changes take place at the menopause, and this statement is associated with the quite erroneous dictum that chronic mastitis is "a disease of the climacteric." It is true that the symptoms of the disease are clinically most obvious at that time, because the cause of the mastitis, whatever it may be, has by then been in operation for a number of years, and also because the breast is at that time being subjected to very irregular hormonic stimuli. The disease must in all cases have begun many years before this, and I see no justification whatever for supposing that the "involution changes" attending the menopause have any connexion with the disease. Moreover, these so-called involution changes are, as I have so often seen them under the microscope, usually nothing more than a simple atrophy. In a breast which has not developed any marked degree of chronic mastitis with cyst formation or abnormal epithelial activity, the acini become smaller and smaller, the lesser ducts tend almost to lose their lumen, and finally most of the glandular lobules disappear altogether. The large ducts always remain, and usually contain secretion; but, except for these, a normal senile breast consists almost exclusively of fibrous connective tissue, which in stout subjects becomes infiltrated with large quantities of fat. There does not seem, therefore, to be much evidence in favour of the involution theory of chronic mastitis, and I think it should be abandoned.

Finally, it has been suggested that trauma may have some influence in initiating a chronic mastitis. I have shown, however, that the changes seen in this disease are diffuse, and clinical experience teaches that the condition is very often bilateral. It is, further, difficult to suppose that any woman could pass 40 years of her existence without being subjected to the ordinary accidents of everyday life, so that a history of trauma can always be obtained by questioning closely enough. Trauma is, in fact, so vague a factor that I do not think it need be further considered.

CAUSE OF MASTITIS TO BE FOUND IN PHYSIOLOGICAL PROCESSES IN THE BREAST.

My consideration of the possible causes of chronic mastitis has been so far purely destructive. I now wish to offer a constructive solution of the problem, which is, however, not yet susceptible of proof. Causes outside the breast do not seem to offer any real help. May there be then any cause within the breast itself? I think the answer to this question is that there may indeed be a cause within the breast, arising in the first place from an inherent defect in its anatomical construction, which reacts in its turn upon the normal physiological mechanisms. It has already been demonstrated that the non-lactating breast is an organ which is subjected to continual physiological stimuli, but which has no outlet for the products of its own activity. A re-absorption of secretion must, therefore, continually be taking place. In addition to this the epithelial lining of both ducts and acini is being constantly renewed and effete cells are being cast off into their lumen. These cells disintegrate and must somehow be removed unless the breast is to become a stagnating mass of epithelial débris. All the available evidence seems to me to point to the fact that the breast is itself continually pouring into the lumen of its ducts and acini a possible source of irritation to which all the pathological changes that I have reviewed may be attributed. Should there be a partial failure in the process of re-absorption of fluid and scavenging of epithelial débris, then any such irritation will become accentuated. This in its turn will further interfere with absorption and may initiate abnormal cellular activity, and so a vicious circle will become established.

I do not pretend to be able to suggest exactly what factors in the body may disturb the physiological balance of secretion and re-absorption. In some individuals the balance may be maintained throughout life. In others—probably the majority—it is upset after being successfully maintained for a considerable number of years; even then there are very wide variations in the degree of irritation produced, and this variation occurs not only as between individuals but also in different parts of the same breast. The variation may be both in the concentration of the irritants formed in the secretions and in the susceptibility of the cells exposed to its action. The reaction of one individual may lie chiefly in the direction of fibrosis; in another it may produce the various forms of abnormal epithelial activity which have already been illustrated. In one case the results of irritation may become apparent after it has been acting for a relatively short time; in another it may be 30 or 40 years before any pathological change can be appreciated. But whatever the source of irritation may be, it is clear that the time factor is of great importance. It has been very commonly observed that an advanced degree of chronic mastitis is seen at an earlier age in women who have never borne children than in women who have passed through the healthful process of pregnancy and lactation, and this is confirmed by the figures already recorded. The explanation of this is to be found in the fact that during lactation the mouths of the mammary glands become unsealed, and the products of activity are removed. If a woman has a large family of children, this natural drainage is established with intermissions for a period of many years, and only as middle age approaches do the breasts again begin to feed upon themselves. For this reason chronic mastitis has been called a disease of the climacteric; but the condition really had its first beginnings when lactation ceased for the last time, perhaps ten years before.

It is worth remarking that recent investigation of the functions of the lymphocyte, the cell so characteristic of chronic mastitis, tends to confirm indirectly this interpretation of the source of irritation in the breast. The lymphocytes in chronic mastitis are, as has been said, very erratic in their distribution, but they are in maximum concentration in a lactating breast when there is any interference with the free escape of milk, and apart from lactation tend to be most numerous in relation to ducts or acini containing much cell débris or fatty secretion. This gains significance from the conclusion arrived at by Dr. S. Bergel,[4] that lymphocytes contain a lipase and are concerned in the digestion of fat and lecithin bodies both in physiological and pathological conditions. The presence and distribution of lymphocytes in the breast thus finds a natural explanation.

THE CHEMICAL PROBLEM.

This explanation of the cause of chronic mastitis in the human being is based entirely on deductive reasoning; but a little thought will show that the hypothesis fits in with all the observed facts both clinical and histological. It cannot, however, be finally accepted until the factor actually responsible for producing a state of irritation has been determined. This introduces an exceedingly difficult problem in biochemistry which can only be dealt with by those who have been specially trained in this line of investigation, and so far as I know little has been done as yet in this direction. It can easily be demonstrated that there are wide variations in the composition of the fluid which is contained in cysts of the breast, or can be expressed from the cut surface of the gland. Commonly a clear green fluid is obtained; sometimes it is brown. Sometimes the fluid is turbid with cell débris; sometimes it is milky and contains both cell débris and fat globules. Occasionally the contents of the ducts or of a cyst are cheesy or almost solid in consistency. This material may consist chiefly of enormous numbers of cast-off cells. Occasionally it may be composed almost entirely of fat, and is probably derived from inspissated milk. A cyst of this nature is known as a galactocele, and is likely to arise in a breast which has attempted to lactate in the presence of a mastitis already well established or of a carcinoma, either condition causing an obstruction of one or more ducts.

The chemical changes which may take place in these stagnating fluids are, as has been said, more or less unknown; but I feel sure that much will be learnt from the investigation of the chemistry of the secretions and of their effect upon the living cells that are exposed for a longer or a shorter time to their influence. Attention has several times been drawn to the analogy between the changes that are found in middle age in the breast and in the prostate,[5] and it is quite possible that chronic mastitis and senile hypertrophy of the prostate are dependent upon similar factors. Light may also be thrown upon abnormal epithelial growth in other organs.

RELATION OF MASTITIS TO CARCINOMA OF THE BREAST.

An immense body of literature has been devoted to the discussion of the relation between chronic mastitis and carcinoma of the breast. This seems to begin with the statement made by Billroth[6] in 1880 that "cancer does not develop in an otherwise normal breast," and culminates in the evidence published by McCarty[7] in 1915. The changes of chronic mastitis were present in every one of 967 cancerous breasts investigated by him. The opinions of many other writers tend in the same direction, and it is, indeed, an almost universally accepted idea that carcinoma of the breast is preceded by the epithelial changes of chronic mastitis. Sir Lenthal Cheatle[8] in several valuable contributions has recently tried to demonstrate this passage from innocent to malignant proliferation, and has even been so bold as to class under the heading of "the prœmial breast" a mammary gland which shows the epithelial changes previously described. But the coexistence of innocent and malignant proliferation does not prove that one necessarily precedes the other. However probable the occurrence of a "precancerous" condition in chronic mastitis may appear, it is exceedingly difficult to furnish any scientific proof of the change, and this has certainly not yet been done.

It has already been mentioned that a great many writers have recorded their observations on the occurrence of chronic mastitis in cancerous breasts, and that McCarty found the association in every one of 967 breasts. It may, in the face of this, seem futile to refer to my own observations, which have been made on only 25 specimens. But even in this short series I have been struck with one or two facts. In these 25 breasts I have found some evidence of chronic mastitis at a distance from the carcinoma in 20, that is 80 per cent. Of the remaining five, three had been infiltrated throughout with the carcinoma, and one was, in addition, lactating, so that it was not possible to form any opinion as to whether chronic mastitis had been associated with the carcinoma or not. It seems to me very extraordinary that this same difficulty should not have occurred in McCarty's series of 967 specimens. The remaining two specimens of my series showed only a senile atrophy in the outlying parts of the breast. I was not therefore able to confirm the 100 per cent. results of some observers.

Another singular fact that forced itself on my attention was that in most cases the breast tissue showed a great increase in epithelial activity close to the advancing edge of the carcinoma, but that this was progressively less, the greater the distance from the malignant infiltration. This proliferation, which resembles that seen in the proliferative type of chronic mastitis, looked as if it were in some way connected with the growth of the carcinoma in close proximity. The well-marked degree of infiltration with lymphocytes usually seen at the growing edge of the carcinoma indicated an inflammatory reaction, and strongly suggested that the malignant cell might be influencing other cells at a distance by means of an abnormal and irritating secretion which induced a cellular proliferation similar to that resulting, as I have suggested, from long exposure to secretions in chronic mastitis, though acting very much more rapidly. If this suggestion were to be substantiated it would explain the apparent association of chronic mastitis with carcinoma in so large a proportion of cases; but it would in no way demonstrate that chronic mastitis is a "precancerous" condition. I cannot offer an opinion that would carry any weight as to the precise relation of chronic mastitis to carcinoma. I can only make the suggestion that carcinoma is not necessarily preceded by chronic mastitis, but that both conditions, or either separately, may result from one cause—namely, prolonged exposure to a chemical irritant such as may be present in the stagnating secretions of the breast.

TREATMENT OF CHRONIC MASTITIS.

In considering the treatment of chronic mastitis I shall not enlarge upon the operative methods of dealing with the more advanced stages of the disease. It is clear that in the present state of knowledge it is wisest to deal radically with the fully-developed type of chronic mastitis with cysts. Complete removal of the gland is sometimes necessary, though it may be remembered that, if there is no reason to suspect the presence of a carcinoma, there is no necessity for removing much, or even any, skin, and that a subareolar operation may be carried out without fear of recurrence. This may still be done even though the massive proliferation of epithelial cells is found to be present. If the disease is apparent as a single cyst or a localised group of cysts, then a local operation is adequate. Some diffuse change will almost certainly be present in the remainder of the breast, but it is always possible that this will not develop further and will not give rise to symptoms of any consequence. The same remark may be applied to a papilloma of a duct-ampulla or to a galactocele.

The treatment of the earlier stages of chronic mastitis in which pain and tenderness, or merely discomfort, are the chief symptoms, presents a more difficult problem. Often there is a psychological factor in the symptoms, and operation is then scarcely ever to be advised. If the trouble is of the intermittent menstrual type, no medical treatment or local application is likely to be of any avail. This type occurs chiefly in young women, and the symptoms may subside of themselves as the patient grows older. Otherwise marriage, followed by pregnancy and lactation, will relieve the patient of her trouble. The more persistent type of chronic mastitis in older patients I have attempted to treat in the way which is logically suggested by the investigations here described. I have first freed the mouths of the ducts in the nipple and opened up their natural outlets by bathing with hot water. Manual pressure combined with a suction bell will then often produce a considerable quantity of the turbid or clear green fluid which is always present in the ducts and dilated acini. The patient is instructed to carry out this treatment systematically, and in a few cases some relief of pain and discomfort has been obtained. But the results are disappointing on the whole. This is not unnatural, for the chronic inflammation has produced fibrosis and other abnormalities in the glandular system, so that efficient drainage of every lobule is no longer possible. The treatment should not be persisted in unless improvement very soon results.

The best results seem to be obtained by the judicious application of X rays. If the proper dosage is applied by an expert, a single treatment will usually have a most satisfactory effect. By this means the secretory activity of the epithelial cells is inhibited or destroyed, and the treatment is again the logical outcome of the interpretation I have put upon the pathology of the disease. The treatment is not new, having often been used empirically in the past, but I have here attempted to put it upon a rational basis.

CONCLUSIONS.

1. The breast is a secreting gland which shows periodical activity from birth to the menopause.

2. The normal, non-lactating breast has no outlet through the nipple for the discharge of its secretions. Secretion must therefore be balanced normally by re-absorption.

3. Chronic mastitis is manifested by dilatation of ducts and acini, accumulation in them of the products of epithelial activity, infiltration with lymphocytes, fibrosis, and epithelial changes. The distribution of all these is very erratic.

4. Chronic mastitis is commonest in women, but occurs also in men. It first appears in the second decade, but is most often seen in the fifth. It appears earlier in single women than in women who have borne children.

5. Chronic mastitis is not bacterial in origin, toxæmic or traumatic, nor is it related to involution changes in the breast.

6. The cause of chronic mastitis is probably to be found in chemical irritation due to stagnating secretions and epithelial débris. This cannot be proved until the chemical changes have been investigated.

7. Chronic mastitis, though very often associated with carcinoma, has not been proved to be "precancerous." Both may be due to the same cause.

8. Chronic mastitis in its more advanced stages must be treated by operation. At an earlier stage natural drainage may be tried, or X rays may be applied.

THE OPERATIVE TREATMENT OF VESICAL DIVERTICULA.*

BY J. SWIFT JOLY, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL FOR STONE; CONSULTING UROLOGIST, WANDSWORTH MUNICIPAL HOSPITAL.

(*With Illustrations on Special Plate.*)

THE treatment of large vesical diverticula is one of the most difficult problems that the urinary surgeon has to grapple with. Complete excision of the sac is, at present, the accepted method of dealing with it, but as so many widely divergent views have been expressed on this subject, it may be of interest to give a brief description of 14 cases upon which I have operated, and the conclusions I have drawn as to the relative values of the different methods employed.

CASE 1.—Male, aged 51, admitted to St. Peter's Hospital Jan. 11th, 1910.

History.—He always had difficulty in micturition, and took much longer to complete the act than other people. Was catheterised in 1901. His bladder was then infected. Since then he has suffered from frequent attacks of pain in the left groin, accompanied by headache, backache, night sweats, marked frequency of micturition, and occasionally by hæmaturia. Frequency of micturition from one to two hours both by day and by night. The urinary stream was slow and weak, but he never had retention of urine. Pain during micturition felt along the urethra.

Condition on Examination.—No stricture. Residual urine 13 oz. Prostate normal; above it the bladder bulged into the rectum, but was not indurated. The bladder could be felt, when it was apparently empty, rising just above the pubis, under the right rectus; when it was distended the displacement to the right was more marked. Urine: Sp. gr. 1018, acid, albumin present, no sugar, urea 1 per cent., deposit of pus and blood. Cystoscopy: Only after a long course of daily irrigation was it possible to wash the bladder clear enough to obtain a satisfactory view. Distension 24 oz. The right ureter was displaced to the right, and the left almost to the middle line. The opening of a large diverticulum was seen above and to the left of the left ureter. It was round, and appeared to be about the size of a lead pencil. Surrounding this orifice, except at its lower part, was a polypoid mass of œdematous mucous membrane. The left ureter was dilated.

Operation.—On the 19th. Trendelenburg position; median incision from pubis to umbilicus, and a transverse one across the left rectus 1½ in. above the pubis. The operation was entirely extra-peritoneal. The diverticulum was about half as large again as the bladder. It completely filled the left half of the pelvis, and extended a short distance to the right of the middle line, pushing the bladder before it. The diverticulum was separated from the surrounding tissues, until the spine of the ischium was reached. A large vein was torn here, and as it could not be picked up and tied this part of the wound was plugged with gauze. The bladder was then opened, and the orifice of the diverticulum identified. It just admitted the first finger, and was about an inch above and to the left of the left ureter. With one finger in the opening the wall of the diverticulum was divided close to the bladder. This incision was carried round the orifice, and the diverticulum was separated from the bladder. This brought the left ureter into view. It was about as thick as the finger, and curved forwards, immediately below the diverticular orifice to its entrance into the bladder. In this portion of its course it was compressed between the diverticulum and the bladder. The diverticulum was now rapidly freed from the remaining adhesions to the rectum and prostate, and removed. The bleeding-points were picked up and ligatured, the wound partially closed, and the bladder and pelvis drained.

Course of Case.—Convalescence was slow and a suprapubic fistula, which tracked down to the diverticular opening, persisted for almost three months. It then closed, but after a short time broke down again. On June 8th he was again admitted to hospital and the sinus excised; at the same time the prostate was enucleated, though it did not appear to be enlarged, as it was thought to have been the cause of the persistent sinus. After this operation the fistula remained closed. In 1913 he was again admitted to hospital and a suprapubic hernia was cured by the filigree method.

This patient eventually died in December, 1920, almost 11 years after his operation, of chronic pyelonephritis, which persisted in spite of treatment. During this interval he had practically no frequency or difficulty in micturition, but there was always a quantity of about 3 oz. of residual urine. The diverticulum, after it was hardened, was about the size of a large orange. Its walls were one-eighth of an inch thick, and were composed of three distinct layers of muscular tissue, lined with transitional epithelium, which was much altered by inflammation (Fig. 7 on Plate).

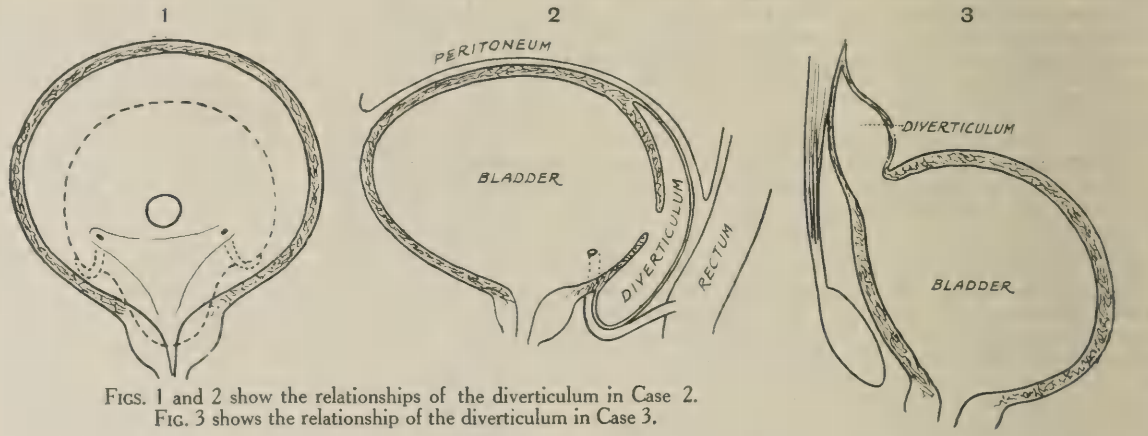
---

* Read before the Section of Urology, Royal Society of Medicine.

Case 2.—Male, aged 53, admitted to St. Peter's Hospital, March 19th, 1912.

History.—Gonorrhœa 30 years before. Developed a stricture, which was easily dilated. Passed a bougie on himself twice a year, but the second time he did so he infected his bladder. Since then had several attacks of cystitis, and his urine always remained turbid.

Condition on Admission.—Slight frequency of micturition. Stream good, some straining towards the end. Occasionally micturition à deux temps. Stricture admitted 17 F easily, and was fully dilated in two sittings. Prostate normal, but a soft elastic swelling could be felt above it. Residual urine varied from 12 to 16 oz. Urine: Sp. gr. 1018, acid, no albumin or sugar, urea 1·9 per cent., deposit pus and bladder epithelium. Cystoscopy: Slight general cystitis. Both ureters normal, clear efflux from both sides. Above the inter-ureteric bar and immediately to the left of the middle line was the opening of a large diverticulum. It was oval in shape with the long axis directed vertically. The cystoscope was introduced into the diverticulum. Its walls were a deep red colour, smooth, and no vessels were visible.



Figs. 1 and 2 show the relationships of the diverticulum in Case 2.
Fig. 3 shows the relationship of the diverticulum in Case 3.

Operation.—On the 22nd. Trendelenburg position. Bladder washed out, emptied as much as possible, and distended with air. Median incision from pubis to umbilicus; peritoneum opened. The diverticulum appeared like an immense bleb on the posterior wall of the bladder, to which it was adherent over a circular area about 3 in. in diameter. The bladder was then opened and it was found that the diverticulum was completely filled with a mixture of urine and lotion. This was mopped up. As it was impossible to find any line of cleavage between the bladder and diverticulum the former was split from front to back. The posterior part of this incision surrounded the orifice of the diverticulum, which was excised. The whole of the epithelial lining of the diverticulum was then removed, also the greater part of its outer wall, leaving only two peritoneum-covered flaps large enough to cover the raw surface. These were stitched in place, and the bladder wound sutured except for a small space left for a drainage-tube. The peritoneal cavity was then closed and the abdominal walls sutured. The ureters first passed downwards between the bladder and the diverticulum, then backwards beneath it, and finally upwards along its posterior surface. They formed ridges visible on the inner surface of the sac, and divided its lower portion into three pouches, a median and two lateral. The deepest portion of the diverticulum reached the level of the middle of the prostate. Its walls were very thin and were composed of a single sheet of muscular tissue lined by epithelium (Figs. 1 and 2).

Course of Case.—The patient bore the operation well and left hospital in four weeks with his wound firmly healed. He returned in three months with a urinary fistula in the scar. He was admitted and the fistula was excised. Since then he has had no further trouble. He was last seen about two years ago. There was no frequency of micturition. The urethra admitted a No. 26 F instrument easily. Cystoscopy: Slight general cystitis. A puckered scar occupied the site of the old diverticular opening, from this a linear ridge ran forwards to the apex of the bladder. Residual urine 2 oz. The urine was slightly cloudy and contained pus and colon bacilli.

Both these cases have already been reported.[1]

Case 3.—Male, aged 49, admitted to St. Peter's Hospital Sept. 2nd, 1912.

History.—Patient was treated for stricture 20 years before. In 1901 he was sounded for stone, but none found. Since then he had an attack of hæmaturia about every six months. For the last few months hæmorrhage at the end of almost every act of micturition. Old-standing cystitis and pyelonephritis.

Present Condition.—Frequency, every hour by day, six or seven times at night. Stream fair, precipitancy, never retention. Urethroscopy: No stricture. Residual urine, 11 oz.; prostate normal. Cystoscopy: Intense cystitis, especially on the base of the bladder. Ureters not visible. Opening of a large diverticulum near fundus just to the left of the air bubble, and of a smaller one to the right of the middle line on the posterior wall. Urine: Sp. gr. 1010, alkaline, albumin present, no sugar, blood small quantity, urea 1·8 per cent., sediment muco-pus.

Operation.—On the 4th. Bladder washed out and distended with air. Suprapubic incision, bladder exposed. Patient then put in Trendelenburg position and peritoneum opened. Diverticulum at apex of bladder running up into urachus. Peritoneum stripped off upper surface of the bladder and off diverticulum. Peritoneal cavity then closed. Bladder opened in middle line, incision prolonged upwards so as to surround diverticular opening. Urachus clamped and divided half way between pubis and umbilicus and diverticulum removed. At this point the urachus was found to be patent and filled with fæculent-looking material. It was followed up to the umbilicus and entirely removed. Bladder sutured round a large tube and abdominal wound closed. Diverticulum on the posterior wall only admitted tip of index finger and was not removed. (Fig. 3 represents the relationship of the diverticulum.)

Patient died, on the twentieth day after operation, of chronic pyelonephritis.

Case 4.—Male, aged 61, admitted to St. Peter's Hospital March 10th, 1915.

History.—Had been treated for stricture on and off for 30 years. Urethroscoped in the out-patient department and no stricture found. Had a poor urinary stream all this time.

Present Condition.—Frequency of micturition every two hours by day, twice at night. Stream poor, straining, stream often interrupted, no precipitancy. Patient had numerous attacks of retention which necessitated catheterisation. No pain except slight scalding on micturition. Cystoscopy: No cystitis, both ureters normal. Orifice of a fair-sized diverticulum above and to the outer side of the right ureter. Prostate slightly enlarged. Residual urine, 2 oz. Urine: Clear, acid, sp. gr. 1018, no albumin or sugar, urea 1·7 per cent., no deposit.

Operation.—On the 12th. Trendelenburg position. Usual suprapubic incision. Diverticulum found to be about the size of a walnut. Freed from adhesions outside the bladder, invaginated into it, and cut away. Gap in the bladder wall sutured with continuous catgut. Prostate enucleated. Bladder closed round a large tube, lateral space drained.

Course of Case.—During convalescence patient developed double epididymitis. Discharged on May 9th. Wound firmly healed. Urine clear, no residual. Frequency four hours by day, once at night.

Case 5.—Male, aged 63, admitted to St. Peter's Hospital April 14th, 1915.

History.—For five years frequency of micturition, sometimes every half hour. Suprapubic lithotomy March, 1914, passed stones soon after his return home. Passed as many as 13 in one day. Litholapaxy in September, 1914, and again in October, 1914. Passed more stones after both these operations.

Condition on Admission.—Frequency every three or four hours by day, twice at night. Stream good but often interrupted, some urgency, no incontinence. No hæmaturia. Urine: Turbid, offensive, alkaline, sp. gr. 1018, albumin present, urea 1·3 per cent., much ropy muco-pus. Bladder intolerant, cystoscopy impossible. Cystogram: Bismuth suspension. Diverticulum size of a hen's egg on right side of bladder. Long narrow neck.

Operation.—On the 16th. Trendelenburg position. Old scar excised, peritoneum opened. With the help of a finger in the peritoneal cavity the peritoneum was stripped off the bladder. Opening in peritoneum sutured and bladder opened. A loose stone was removed. Diverticulum found to be packed with calculi, which were removed. It was about the size of a hen's egg, and extended downwards to base of bladder. The ureter curved downwards and forwards, first behind and then below the orifice of communication. The diverticulum was very adherent but was freed and removed from outside the bladder. Gap in bladder wall closed with two layers of continuous sutures. Pre-vesical space and bladder drained, rest of wound sutured. The orifice of the diverticulum just admitted the index finger. It was about half an inch above and to the outer side of the right ureter.

Course of Case.—Convalescence uneventful. Patient discharged on May 26th. Wound soundly healed. No frequency of micturition. Urine still turbid. No residual urine.

CASE 6.—Male, aged 72, admitted to St. Peter's Hospital Sept. 1st, 1915.

History.—Frequency of micturition and straining for three years. Prostatectomy January, 1914. Was treated for cystitis March and April, 1914. His condition improved for a few weeks, then grew steadily worse.

Condition on Admission.—Frequency every ten minutes by day, every 45 minutes by night. Stream dribbling, great straining. Occasionally passed clots. Severe pain along the urethra during micturition. Urine: Turbid, ammoniacal, urea 1·4 per cent., much muco-pus, albumin present. Cystogram: Bismuth suspension. Bilateral diverticuli, each about the size of a walnut, standing well out from the bladder.

Operation.—On the 3rd. Trendelenburg position. Old scar excised. Bladder very adherent to surrounding structures, especially to the posterior surface of the pubis. Adhesions divided and bladder opened. The orifices of the diverticula were symmetrically placed, each about an inch above and to the outer side of the corresponding ureter. Bladder wall split down to the orifices and the diverticula dissected free and removed. Bladder wound closed round a large tube and each lateral space drained. The whole operation was rendered difficult and tedious on account of adhesions.

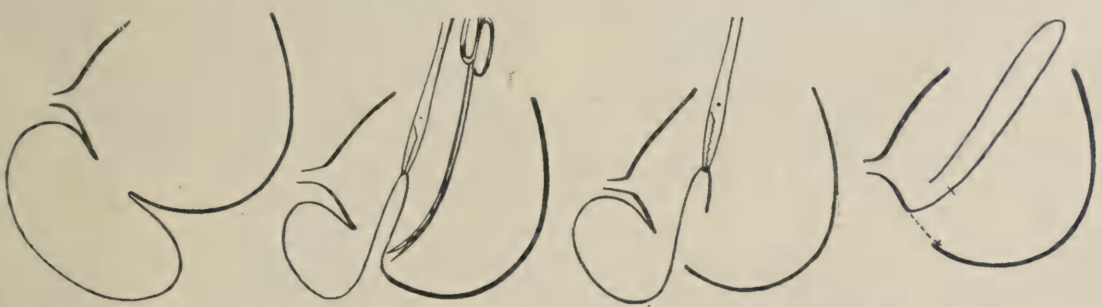


FIG. 4.—Stages of the operation for invagination of the diverticulum in Case 8. The dotted line in the last diagram indicates the flap of substance of the sac left in place and stitched over the defect in the bladder.

Course of Case.—Patient discharged from hospital on the 29th. Wound firmly healed, frequency two hours by day and night. Attended the out-patient department for a few months, during which time his urine became clear and he lost his frequency of micturition.

CASE 7.—Male, aged 49, admitted to St. Peter's Hospital June 20th, 1915.

Condition on Admission.—Frequency of micturition eight to ten times during the day, twice at night. Pain along the urethra during the act. No stricture, no enlargement of the prostate. Urine: Bacilluria, no albumin or sugar, urea 1·1 per cent. Residual urine 9 oz. Cystoscopy: Base of bladder and all round the internal meatus œdematous. Opening of a diverticulum just above and to the inner side of the right ureter. Ureteric orifices normal in appearance.

Operation.—On the 23rd. Trendelenburg position. Bladder widely opened. Diverticulum admitted index finger to a depth of almost 3 inches. Incision round orifice and diverticulum freed by blunt dissection. A ½-inch tube passed through the bladder and into the space from which the diverticulum had been removed. Gap in bladder sutured round it. Bladder drained.

Patient discharged August 4th. Wound healed, no residual urine, no frequency.

CASE 8.—Male, aged 71, admitted to St. Peter's Hospital August 23rd, 1919.

History.—Fifteen years before had some difficulty in passing urine for three or four days. Well until April, 1919, when sudden retention of urine occurred, followed by a severe fit of shivering. Catheterised. Since then on complete catheter life, passing the instrument three or four times a day and once at night. Previous to April, 1919, frequency every two hours by day and every hour by night.

Condition on Admission.—Decidedly senile. Per rectum, prostate not enlarged. Cystoscopy. Slight intravesical projection of prostate. In the neighbourhood of right ureter, round orifice of an enormous diverticulum. Orifice about the size of a shilling, cavity very dirty. Right ureter could not be seen, left normal in position. Severe general cystitis. Cystogram: Thorium solution. Oblique position showed a double cavity, with the diverticulum low down in the right side of the pelvis. It was about the same size as the bladder. Antero-posterior position, showed cavity overlapping bladder, and extending far to the right. Urine: Sp. gr. 1010, acid, albumin and sugar present, urea 0·3 per cent., 183 gr. passed in the 24 hours.

Operation.—On Sept., 5th. Stovaine. Trendelenburg position. Median incision from pubis to umbilicus, bladder widely opened. With the hand in the bladder, the finger could just reach to the bottom of the sac. An attempt was made to invaginate the diverticulum into the bladder, by blunt dissection from without, aided by traction by means of a volsellum passed through the orifice. Dense adhesions binding the sac to the seminal vesicles, prostate, and rectum made it impossible to complete this invagination; however, the upper wall of the diverticulum was completely invaginated. A semicircular incision was then made, severing the upper portion of the neck of the sac (Fig. 4), and the diverticulum was inverted through this opening. This made it possible to reach its outer wall, and the surrounding tissues were then easily separated off by means of gauze dissection. The whole of the diverticulum was by this means turned inside out, and invaginated into the bladder. It was so large that more than half of it came through the abdominal wound. As the vesical orifice of the right ureter had never been identified, the ureter itself was exposed in the pelvis and opened. A catheter was passed down it, and appeared between two folds of mucous membrane, just within the diverticulum, opposite the lowest point of the opening. The sac was then cut away, except for a small semicircular flap surrounding the ureteric orifice. This flap was stitched over the defect in the bladder. The ureter was sutured, and the bladder wound closed round a large tube. The lateral vesical space was drained, and the abdominal wound closed round the tubes.

Course of Case.—The patient bore the operation well, but convalescence was slow. The suprapubic sinus closed after a catheter had been tied in for a fortnight. Patient sent to a convalescent home on Oct. 25th. Wound healed, but patient entirely dependent on his catheter.

Condition on Readmission.—April 10th, 1920. On catheter life since operation. Prostate: lateral lobes slightly enlarged, smooth, and movable. Cystoscopy: Shallow depression at sight of diverticular orifice. Small intravesical pro ection of middle lobe of prostate. Severe chronic cystitis. Urine: Sp. gr. 1020, acid, small quantity of albumin, moderate quantity of sugar, cloudy yellow colour, deposit of mucus. Phenolsulphonephthalein (intravenous injection) appeared in three minutes; 44 per cent. excreted in the first half-hour, and 11 per cent. in the second. Urea-concentration test: 1·9 per cent. in the second hour, and 1·7 per cent. in the third.

Operation.—Prostatectomy, on the 23rd. Stovaine. Bladder opened after it had been freed from the pubis. Peritoneum pushed upwards from the scar. Small prostate easily enucleated. Very little bleeding.

Course of Case.—Patient discharged on May 18th. Wound healed. Frequency two hours by day, twice at night. Residual urine one ounce. Urine turbid. He attended the out-patient department for a few months. General condition improved very much. Frequency normal. I heard from this patient on March 20th, 1923, as follows: General health good; no retention; frequency four hours by day, three times at night; stream good, urine clear; no pain or leakage through scar.

CASE 9.—Male, aged 50, admitted to St. Peter's Hospital Dec. 28th, 1920.

History.—Difficulty in micturition for 12 months, which was steadily getting worse. Frequency every hour by day, not at all during the night. Had cystotomy done one month before for over-distension, told he had a large pouch in his bladder.

Condition on Admission.—Suprapubic sinus through which all the urine came. Urine very foul, sinus surrounded by unhealthy granulations. Prostate slightly enlarged, hard nodule right lobe, whole gland movable.

Operations.—Cystotomy on the 31st. Sinus enlarged, opening of a large diverticulum found just outside right ureter. Bladder very foul, almost pure pus coming from diverticulum. Tube inserted into sac, and another into bladder. Daily irrigations. Excision of diverticulum, Jan. 14th, 1921. Stovaine and general anæsthesia. Trendelenburg position. Bladder widely opened, and freed from adhesions. Contents of diverticulum still very foul. Diverticulum freed from surrounding structures, invaginated into bladder, and removed. Operation very difficult on account of dense adhesions. Gap in bladder sutured. Suprapubic wound closed round large tube. Lateral vesical space drained.

Course of Case.—Patient discharged on March 13th. Slight suprapubic leak. Passing urine freely and without pain. On June 21st he was readmitted, with double pyelonephritis. Sinus enlarged, de Pezzer tube inserted. Patient sent to infirmary. (As I was out of town, I did not see this patient on his readmission.)

CASE 10.—Male, aged 51, admitted to St. Peter's Hospital June 26th, 1920.

History.—Frequency of micturition for two years, gradually getting worse. Difficulty in micturition for one year. Ten weeks before admission, complete retention. Metal catheter passed under general anæsthesia, but as it could not be passed a second time a perineal section and suprapubic cystotomy was performed. A diverticulum was then discovered. Bladder drained for ten weeks "in the hope that the diverticulum would contract." Venereal disease denied.

Condition on Admission.—Suprapubic and perineal fistulæ; most of the urine came through the former opening. Per rectum, prostate not enlarged. In the region of the left seminal vesicle a soft, elastic, sausage-shaped tumour was felt. It appeared to be adherent to the pelvis. Urine: Sp. gr. 1020, cloudy yellow, acid, albumin present, no sugar, deposit of pus. Urea concentration test, 1·65 per cent. in the second hour.

Operations.—(1) On July 2nd (stovaine), urethra easily dilated to 14/16, and 22 F. catheter tied in. Perineal wound allowed to heal. On the 23rd (2) cystotomy (stovaine and ether). Scar excised, and bladder opened. Diverticulum discovered on the left side. Opening about an inch above and to the outer side of left ureter. It easily admitted the index finger. Cavity very large, about the size of the clenched fist, was filled with exceedingly foul pus. Tube inserted into diverticulum and another into the bladder. Wound partially closed. Continuous irrigation was attempted, the fluid entering through the tube in the diverticulum and returning by the bladder tube, but it failed, as the diverticular orifice contracted round the tube placed in it and did not allow the fluid to circulate. (3) Excision of diverticulum on the 28th (stovaine, and ether after the first hour). Cystotomy wound reopened. Bladder wall very thick and indurated, which made it difficult to expose the interior of the viscus. Much peri-cystitis. Left lateral wall split down to the diverticular orifice. Sac very adherent, and was torn during removal, but the whole of it was got away. Peritoneum twice torn and sutured. Left ureter localised, and kept from injury. Left vas cut across. Bladder sutured round a large tube. Lateral space drained. Fowler position, Murphy's rectal drip.

Course of Case.—Patient discharged from hospital August 30th, 1920. General condition good. Wound soundly healed. Urine acid, slight deposit of pus. Could hold urine for two or three hours. Residual less than one ounce. On March 20th, 1923, I heard from this patient as follows: General health fair; frequency by day six times, once at night; urine clear, no pain, stream fair, no leakage through wound.

CASE 11.—Male, aged 53, admitted to St. Peter's Hospital March 4th, 1922.

History.—Since 1915 frequency of micturition, later difficulty and straining. Urgency and some incontinence for three years. For four months has catheterised himself every day, but was able to pass a small quantity of urine naturally.

Condition on Admission.—No stricture. Prostate slightly enlarged, soft, elastic, could be felt bimanually, freely moveable. Cystoscopy: Residual urine 9 oz. Very marked trabeculation. Numerous small saccules. Diverticulum on right side, at junction of posterior and lateral walls. Stone in post-prostatic pouch. Ureteric orifices not seen on account of intra-vesical projection of middle lobe of prostate. No cystitis. Urine, clear, acid, sp. gr. 1017, no albumin or sugar, daily urea 1·8 per cent., urea concentration test 3 per cent. Cystogram: Sodium iodide solution. Large diverticulum right side, long narrow neck. Numerous small saccules, especially near the base of the bladder.

Operation.—On the 15th. Suprapubic incision. Calculus removed. Bladder wall very thick, much peri-cystitis. Bladder wall split down to orifice of diverticulum, and sac excised. Right ureter and vas adherent to it. Prostate enucleated, and prostatic cavity packed with gauze. Wound in bladder sutured round a half-inch tube. Small tube in lateral space. Wound closed.

Course of Case.—On April 15th patient discharged from hospital. General condition excellent. Suprapubic wound healed, passing water freely per urethram. This patient was seen on Feb. 26th, 1923. Frequency four hours by day, occasionally once at night. Residual urine 1½ oz. Urine slightly cloudy. General condition very good.

CASE 12.—Male, aged 37, admitted to St. Peter's Hospital April 1st, 1922.

History.—Eighteen months before, pain in the hypogastrium, which had no relation to micturition. Six months later frequency and difficulty in micturition. Frequency then seven or eight times by day, twice or three times by night. Stream poor, only a small dribble, urgency. April, 1921, acute retention, lasted two days. Similar attack next month. July, 1921, suprapubic cystotomy for stone, but none found. Since then had passed a catheter once or twice a day on himself.

Condition on Admission.—Weak suprapubic scar, which broke down from time to time, and leaked urine. Bladder easily palpable when distended. Catheter life. Prostate normal. Cystoscopy: Distension 22 oz. Chronic cystitis, especially in region of trigone. No trabeculation. Two diverticula: (1) just above and to the outer side of the left ureter, contents turbid, orifice about the size of a lead pencil; (2) small one just above right ureter. Trigone displaced to right so that the left ureter lay almost in the middle line. Both orifices normal. Œdematous mucous membrane round orifice of large diverticulum. Both ureters catheterised. Clear urine from both kidneys. Urea concentration test, both kidneys gave 3·0 per cent. concentration. Same test applied to bladder urine gave 1·42 per cent. Internal urethral orifice normal. Cystogram: Sodium iodide solution. Twenty ounces of fluid injected. Bladder displaced to the right. Very large diverticulum filling up left half of true pelvis (Fig. 5). Bladder emptied as much as possible by catheter, and second exposure made. Diverticulum still distended, and a small amount of fluid in the bladder itself. (Fig. 6.) Urine: Turbid, alkaline, no albumin or sugar, daily urea 1·8 per cent. in 50 oz., or 306 gr.

Operation.—On the 19th. Left ureter catheterised. Trendelenburg position. Scar excised, bladder freed from pubis and opened. Diverticulum freed by blunt dissection, and gradually invaginated into bladder. Left ureter lay behind and below neck of sac, and was separated off. Diverticulum together with a small portion of bladder wall surrounding neck removed. Gap in bladder sutured. Lateral space drained, large de Pezzer tube in bladder. Wound closed. Diverticulum on right side too small to admit tip of finger, not removed.

Course of Case.—On May 8th patient discharged from hospital. Wound healed. Micturition normal. Frequency three hours by day, once at night. Residual urine 1½ oz.

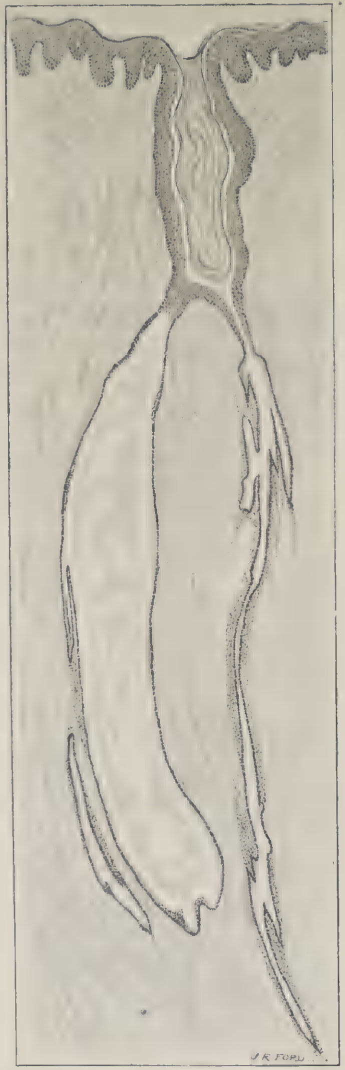

FIG. 1.—Longitudinal section of a duct mouth into which two collecting ducts open, one being distended with secretion. The epithelial plug is shown in relation to the squamous-celled lining of the mouth. (× 20.)

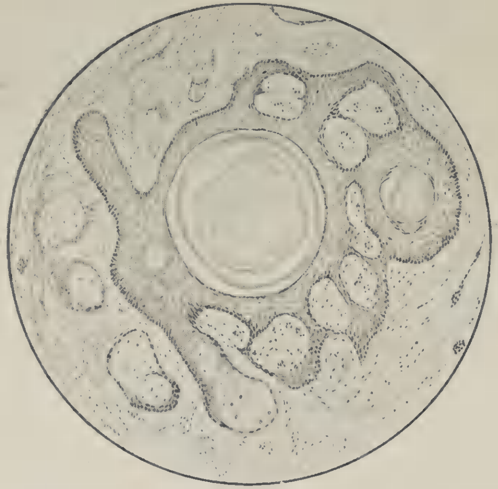

FIG. 2.—Transverse section (paraffin) of mouth of a duct, showing laminated epithelial plug in position

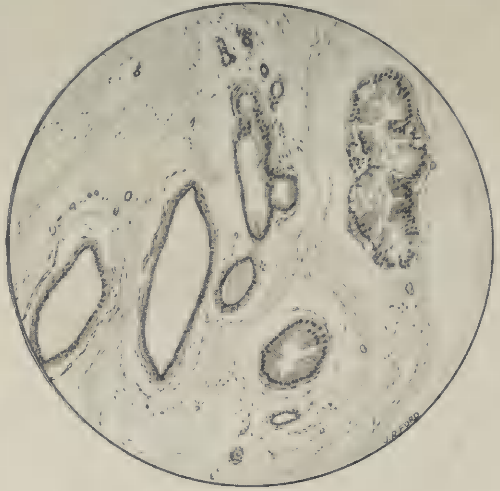

FIG. 3.—A group of ducts and acini, with swelling of epithelial cells in some and distension of others.

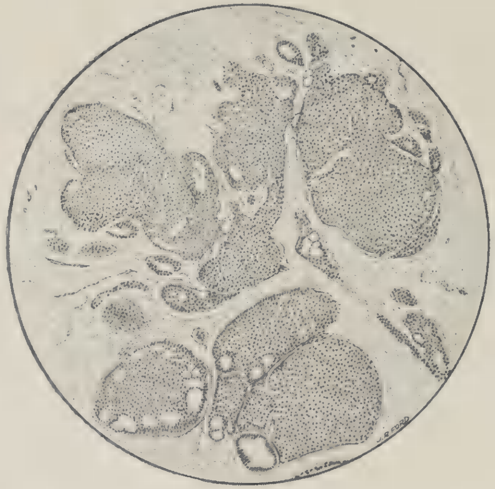

FIG. 4.—Massive epithelial proliferation in an advanced stage. A few acini can still be seen.

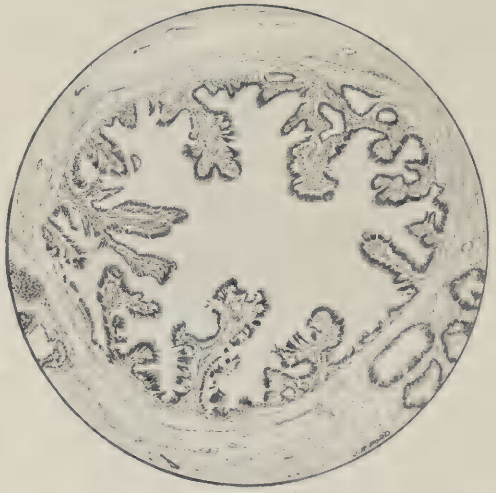

FIG. 5.—First stage of formation of papillomata in a duct. The epithelial cells are swollen.

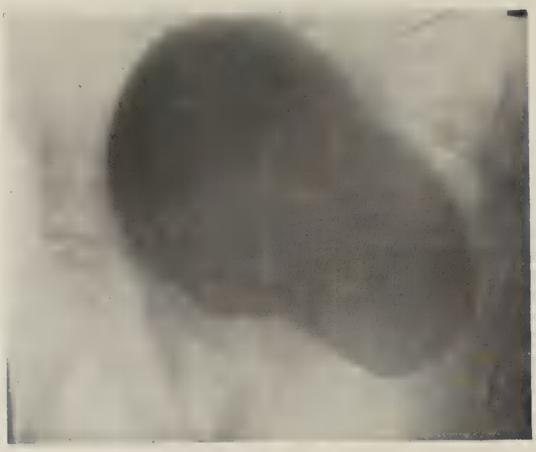

Fig. 5.—Cystogram of Case 12 (sodium iodide solution) showing very large diverticulum filling up left half of true pelvis.

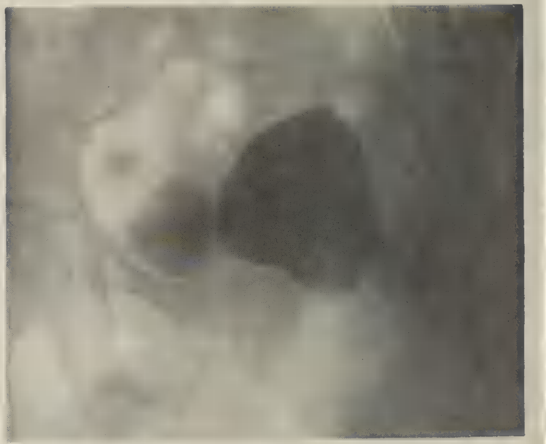

Fig. 6.—Second cystogram of Case 12 taken after bladder had been emptied as much as possible by means of a catheter. Diverticulum still distended with the sodium iodide solution, a small quantity of which also remained in the bladder.

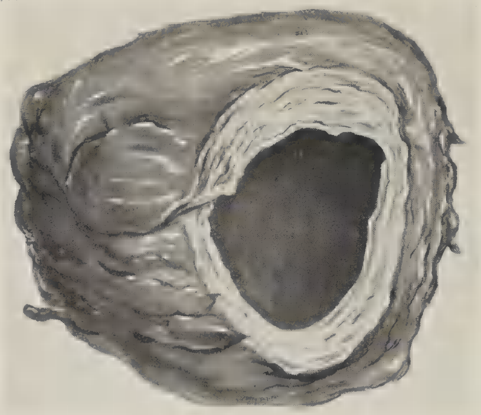

Fig. 7.—Diverticulum removed from Case 1.

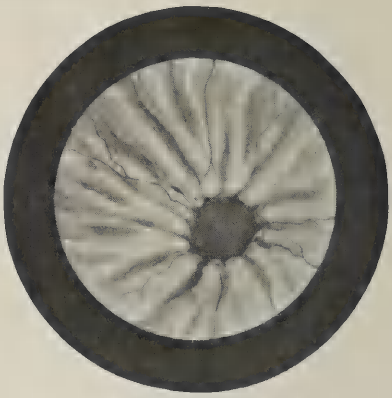

Fig. 8.—Typical appearance of a diverticular orifice as seen through the cystoscope.

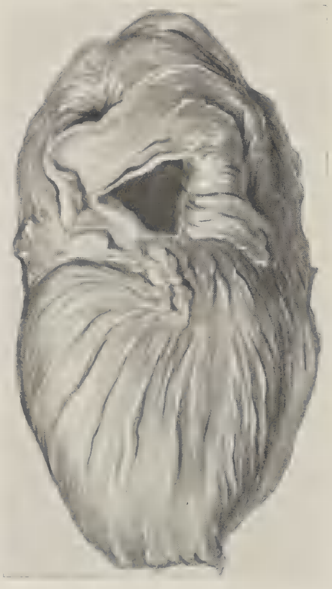

Fig. 9.—Diverticulum removed from Case 13.

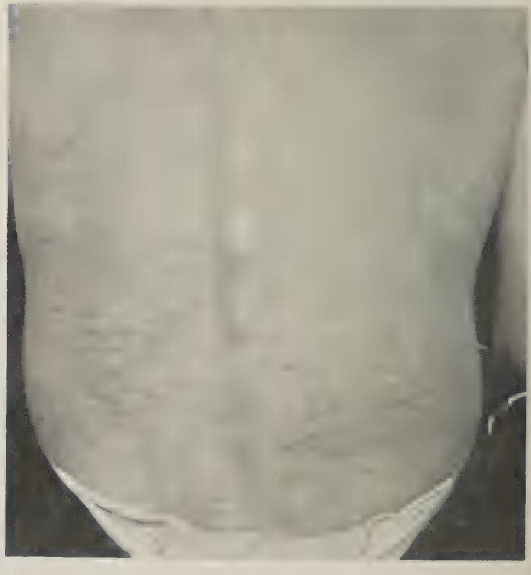
DR. BEDO HOBBS: STRIÆ DISTENSÆ.



Case 3, showing the striæ scattered all over the lower thoracic and lumbar regions.

On March 20th, 1923, I heard from this patient as follows: General health steadily improving since operation; frequency three or four times by day, twice by night; stream "splendid"; no pain; wound soundly healed.

CASE 13.—Male, aged 62, admitted to St. Peter's Hospital Jan. 5th, 1923.

History.—Ten years ago hæmaturia after straining at stool. Since then pain "in the bladder" whenever he has a cold, and occasionally a trace of blood in the urine. Five years later frequency and difficulty in micturition. Soon afterwards catheter life, passing the instrument twice or three times a day. Cystoscoped in 1912, and told "he had a sac." Admitted to St. Peter's Hospital Oct. 20th, 1919. Prostate removed; discharged Nov. 27th. Had intense cystitis at the time, and diverticulum apparently not noticed on cystoscopy. Suprapubic wound took 22 months to heal. Patient washed his bladder out every day with nitrate of silver by Janet's method. Had slight hæmaturia shortly after leaving hospital, and passed several small stones.

Condition on Admission.—Frequency of micturition, six times by day and twice by night. Micturition normal, stream and projection both good. Abdomen: Suprapubic scar, weak in its lower portion. When bladder was distended, it could be felt in right iliac fossa. Right kidney not palpable, left completely palpable, movable, enlarged, painless. Cystoscopy: Residual urine 30 oz. Bladder capacity 50 oz. Generalised cystitis with irregular bulging and sacculation. Right ureteric orifice active, fairly healthy, left large, patent, never closes. Opening of diverticulum fairly high up on the left side, difficult to see because left wall of bladder was pushed almost to middle line by the diverticulum. It appeared to be about the size of a sixpenny piece. Cystogram: Sodium iodide, 5 per cent. solution; 48 oz. injected. Enormous bladder pushed over into right iliac fossa. Diverticulum filled left side of true pelvis. Small slit-like space between bladder and diverticulum. Narrow orifice of communication. When bladder had been emptied as much as possible by means of a catheter, diverticulum remained nearly full, and there was still some fluid in the bladder itself. Urine: Hazy, sp. gr. 1012, alkaline, no albumin or sugar, daily urea 1·0 per cent. in 75 oz., or 322 gr. Urea-concentration test 1·5 per cent. in 3·5 oz., or 22 gr.

Operation.—On the 10th. Old scar excised and bladder opened. Trendelenburg position. Orifice of diverticulum about three-quarters of an inch in diameter, situated about an inch above and to outer side of left ureter. Catheter passed up left ureter. Diverticulum freed by finger and gauze dissection, and removed from outside the bladder. Gap in wall sutured by two layers of continuous catgut sutures. Internal urethral orifice about the size of a lead pencil, but was incised, as there was a "shelf" above prostatic cavity. Marion's tube in bladder, lateral space drained. Wound closed, catheter tied in. Fig. 9 (on Plate) shows the diverticulum after removal.

Course of Case.—Patient discharged from hospital Feb. 19th. Wound firmly healed. Micturition normal, no frequency. Residual urine ½ oz. I saw this patient on March 12th, 1923. General condition excellent. Micturition normal. Frequency four hours by day, once at night. Urine clear, a few small flakes in it.

CASE 14.—Male, aged 69, admitted to St. Peter's Hospital Jan. 7th, 1923.

History.—Three years ago difficulty in starting micturition. A few months later pain at tip of penis before and during act. Nocturnal frequency for 18 months. Complete retention two years ago.

Condition on Admission.—Bladder distended to umbilicus. Micturition, much straining, delay, and pain. Stream in drops only, some after-dribbling. Prostate only slightly enlarged, rather firm. No stricture. Put on regular catheterisation, 18 oz. being drawn off each time the instrument was passed. Urine: Turbid, alkaline, sp. gr. 1022, no albumin or sugar, much pus, daily urea 2·5 per cent. in 30 oz., or 327 gr. No cystoscopy when in hospital on account of over-distension.

Operations.—On the 10th, suprapubic cystotomy. Trivial intra-vesical projection of prostate. Diverticulum size of a hen's egg, above and to the outer side of left ureteric orifice. De Pezzer tube inserted. On the 24th, diverticulum excised from outside bladder. It was very adherent. Gap in bladder wall sutured with two layers of continuous catgut. Some thick peri-vesical fat sutured over opening. Prostate size of a cherry enucleated. It was fibrous, and contained several small calculi. Cavity packed. Marion's tube in bladder. No tube in lateral space.

Course of Case.—Sharp attack of secondary hæmorrhage on fourth day. Feb. 5th, large abscess left side of bladder. Tube inserted. Since then did well. On March 7th he passed urine naturally, but fistula not quite closed. On the 20th, still in hospital.

The Relative Values of the Different Operative Methods.

It is universally admitted that the only satisfactory treatment of this condition is excision of the sac, but there is a considerable divergence of opinion as to the best method of performing the operation. Before discussing this question, however, I wish to point out the dangers of a preliminary cystotomy in these cases. A cystotomy does not drain the diverticulum. When the bladder contracts round the cystotomy tube, the diverticular orifice closes, and the cavity is completely shut off from the bladder. Under these conditions no amount of vesical irrigations will disinfect the diverticulum, and its contents invariably suppurate. The deplorable condition that patients Nos. 9 and 10 were in when I first saw them was undoubtedly due to this cause. In both cases I tried to control the suppuration within the diverticulum by passing a tube into the sac through its vesical orifice, but in neither case was it possible to wash out the sac into the bladder, or the bladder into the sac. Each cavity could be washed out independently of the other, but this was not satisfactory, and in both cases I was forced to operate while the sac was still in a filthy condition. The walls of these sacs have practically no power of contraction, and remain in an inert flaccid condition, which predisposes them to stagnation and infection. When I am called upon in future to deal with such grossly infected diverticula I shall, as a preliminary to excision, open the bladder, and pass two small tubes into the sac, as well as leaving a larger one in the bladder itself. Continuous irrigation can then be carried out, the fluid entering the diverticulum by one small tube, and leaving it by the other. It is in many cases possible to drain the diverticulum independently of the bladder, but I see no advantage in this procedure. If the diverticulum lies below and behind the bladder, it can only be satisfactorily reached from the perineum, and this perineal drainage may render subsequent removal of the sac exceedingly difficult, if not impossible. I consider that a preliminary cystotomy should not be done, except when the kidneys are damaged so severely that it is obvious that the patient would not stand a primary excision. Even in these cases the bladder should only be drained for as short a time as possible, and means must be taken to drain and irrigate the diverticulum independently of the bladder.

Turning to the operation of excision, I feel that no set operation is suitable for all cases, but I think there are certain broad indications which would lead the surgeon to choose beforehand the operation best suited to the particular case. I also feel that it is not always possible to make a definite plan of campaign until the bladder has been exposed, as so much depends on the amount of peri-cystitis present, and on the number and density of the adhesions binding the diverticulum to neighbouring structures. One can learn the size and position of the orifice, the amount of trabeculation of the bladder wall, and the severity of the infection by means of cystoscopy; and the size, position, and to a certain extent the relationship of the diverticulum by means of cystograms; but one has no means of telling beforehand whether the sac is bound down by adhesions, or lying free in the fatty tissue of the pelvis. With regard to the operation itself, diverticula may be excised: (1) from the outer surface of the bladder; (2) by splitting the bladder wall down to the orifice of the diverticulum; and (3) from within the bladder.

(1) *Excision from Without the Bladder.*—This operation is best suited for diverticula situated high up on the lateral walls of the bladder, and for those occurring at the urachus. The operation may be either trans- or extra-peritoneal. A trans-peritoneal operation is indicated if the orifice of the diverticulum lies above the line of reflection of the peritoneum from the bladder wall, but these cases are not common, as the orifice is usually situated well below this level. In some cases it is a help to open the peritoneum when stripping it from the upper wall of the diverticulum,

but if this is done the bladder should not be opened until the abdominal cavity has again been closed. I have performed this operation on five of my cases (Nos. 1, 3, 5, 13, 14); in two of them (Nos. 3 and 5) I opened the peritoneum to facilitate stripping it back from the wall of the sac. The operation is facilitated if the bladder is opened and one finger placed in the diverticulum, while the upper and outer walls of the sac are cleared by gauze dissection. When the operator is dealing with the lower portion of the diverticulum, the finger in the sac is of no further assistance. The wall of the diverticulum is then grasped low down by means of a volsellum, and aided by traction on it the dissection is completed. I have not found it any advantage to plug the sac with gauze, and if the diverticulum lies low down in the pelvis, it is a positive disadvantage. The plug fills up almost the whole of the narrow space one has to work in, and renders the dissection much more difficult. I have tried this method on several occasions, and always had to remove the gauze again in a few minutes. This operation is rendered difficult if the bladder walls are thick and indurated, if the diverticulum is also thick-walled, and if there is much peri-cystitis.

(2) *Splitting the Bladder Wall down to the Orifice of the Diverticulum.*—This operation was first described by me in a paper read before the Urological Section of the Seventeenth International Congress of Medicine, which met in August, 1913,[2] and quite independently by Marion in November of the same year.[3] In my case, however, the operation was trans-peritoneal, while in Marion's it was extra-peritoneal. The idea underlying both these operations was the same, and was an attempt to obtain better exposure of the deeper parts of the diverticulum. I performed this operation in Case 2 (trans-peritoneally), and in Cases 6, 10, and 11 (extra-peritoneally). Case 6 was one of bilateral diverticula, and both sides of the bladder were split down to the necks of the diverticula. The incision is really a racquet, with a long handle and a small blade, as the orifice of the diverticulum is encircled, and a small portion of the bladder wall removed with the sac. The operation is indicated: (1) in cases where the diverticulum is situated low down on the posterior wall of the bladder; (2) when the walls of the bladder or diverticulum are thick and inelastic; and (3) when there is marked peri-cystitis. Case 2 came under the first category, and I do not think I could have removed this diverticulum by any other means. In Cases 6, 10, and 11 troublesome adhesions were present, due in the first case to a previous prostatectomy, in the second to a prolonged suprapubic and perineal drainage, and in the third to marked peri-cystitis. In Cases 6 and 11 the bladder walls were very thick. A rough estimate of the thickness of the bladder wall can sometimes be obtained by means of a simple cystogram. In every case of vesical diverticulum I have seen the walls of the bladder and of the diverticulum are in contact with each other round the diverticular opening. This means that the length of the neck of the diverticulum is equal to the combined thickness of these two walls, so that if the diverticular shadow lies at a considerable distance from that thrown by the bladder, and the two are only connected by a long isthmus, it is fairly safe to assume that the bladder walls are thick. I may also add that the walls of the bladder are always thicker than those of the diverticulum.

(3) *Intra-Vesical Operations.*—(*a*) Encircling the orifice by an incision through the whole thickness of the bladder wall, and removing the diverticulum by blunt dissection. I have only performed this operation once (Case 7), and have completely given it up, as I consider it dangerous. It is only suited for small diverticula, and is dangerous, as there is a great risk of wounding the ureter, which always lies in close relationship with the neck of the diverticulum.

(*b*) Invagination of the sac. This operation should be performed partly from inside the bladder and partly from outside it. It is a dangerous procedure to insert a volsellum through the diverticular opening, seize the fundus of the sac, and attempt to invaginate it. One operator drew a loop of small intestine into the bladder by this method, but fortunately discovered his mistake before dividing the neck of the sac. If it is decided to remove a diverticulum by this method, the upper wall of the sac should first be cleared as far as possible from the outer side of the bladder, and also from the surrounding structures. This portion of the diverticulum should then be invaginated through the orifice and seized from within. The dissection can then be completed from without, while traction is made by means of a volsellum gripping the portion already invaginated. This operation is only suitable for thin-walled diverticula that are comparatively free from adhesions. Young employs suction to invaginate the diverticulum.[4] This method requires an electric pump, as the suction obtained by means of a Sprengel's pump is quite insufficient for the purpose. I have performed the operation of invagination in three cases (Nos. 4, 9, and 12); I attempted it in Case 13, but was unable to complete the invagination, so I turned the sac back and removed it from outside the bladder.

(*c*) Combined invagination and inversion of the sac. This operation has been fully explained when describing Case 8, so I need not recapitulate it. I believe this method has not been described before, and I consider it a definite advance on the usual invagination method. As a matter of fact, I failed to invaginate the sac in this case, and I think I should have been unable to remove the diverticulum if I had not thought of inverting it. It can be employed in diverticula springing from any part of the bladder, but is particularly useful for dealing with large sacs situated deep down in the pelvis. It is eminently safe, as the outer surface of the diverticulum is well seen while the adhesions are being separated from it. It cannot, of course, be employed in cases where the wall of the sac is too stiff to allow of invagination, but this is the only definite contra-indication.

Operative Treatment in Cases Complicated by Enlarged Prostate.

Cases of vesical diverticula have frequently been diagnosed as enlargement of the prostate, and the gland has been removed before the presence of the diverticulum was suspected. This happened in Cases 6 and 13 of my series. I feel that in both these cases the patient's condition was rendered worse by this procedure. I have already alluded to the bad results obtained in cases where the bladder has been simply drained, and everything I have said regarding cystotomy applies with equal force to prostatectomy. I feel that the ideal procedure is to remove both the diverticulum and the prostate at the same sitting. This was done in Cases 4, 11, and 14 with excellent results. If, however, it puts too great a strain on the patient's powers of recuperation, the diverticulum should be removed at the first sitting, and the prostate enucleated as soon afterwards as is feasible. This course was followed in Case 8. Lastly, if the patient's condition is so poor that he will not stand any major operation, the bladder should be opened and independent drainage provided for the diverticulum in the manner already described. Even under these circumstances the preliminary drainage should be of as short a duration as possible.

Vesical Diverticula Complicated by Stone.

(1) *Calculus Lying Free in the Bladder.*—The mere removal of such a stone is never a complete operation. There may be others in the diverticulum. Even if there are none the diverticulum remains, and will probably give rise to symptoms. I do not think that a litholapaxy should ever be performed where there is a definite diverticulum. A case on which I operated some years ago illustrates this point. The patient had a stone about the size of a filbert lying free in his bladder, and on cystoscopy a small shallow diverticulum was seen just to the outer side of the right ureter. I thought it was too small to give rise to any symptoms, and so decided to crush the stone. It was

caught with the lithotrite, but when I commenced to crush it, it slipped out of the jaws of the instrument and I could not find it again. I then cystoscoped the patient and found the stone in the diverticulum. The bladder was opened and the stone removed from the sac, which was just large enough to hold it comfortably. The orifice of the diverticulum was then enlarged downwards and the wound closed. What happened to the whole calculus in this case may easily happen to fragments in others, and I feel sure this is one of the causes of recurrence in these cases. Case 5 also bears out this point. He underwent a suprapubic lithotomy and two litholapaxies in the space of about a year, yet when I operated there was a stone lying free in his bladder, and the diverticulum was packed full of them. I feel strongly that the correct procedure in all these cases is to open the bladder, remove the calculus, and excise the diverticulum.

(2) *Stone in the Diverticulum.*—Here the indications for removing the diverticulum are even stronger. Mere removal of the calculus may make the patient's condition worse, just as a simple cystotomy does. A very interesting case illustrating this point has been described by Kummer and Brutsch.[5] Their patient suffered from the usual symptoms of stone for over 20 years. He never had retention, and there was only a small quantity of residual urine. A stone was felt in his bladder, and the diagnosis confirmed by radiography, which showed a shadow filling up the greater part of the true pelvis. The bladder was opened and two calculi were found lying free in it, while a third was seen projecting from the orifice of a very large diverticulum, which it filled completely. They were all removed, but the diverticulum was left in situ. After the operation the patient was absolutely unable to pass urine naturally, and had to rely on self-catheterisation. The authors came to the conclusion that his retention was not due to atony of the bladder, but to the presence of the diverticulum. They advised an operation for its removal, but the patient refused it. If possible the diverticulum and the stone in it should be removed at the same sitting, but if the patient's condition will not stand this operation, one must remove the stone first. In this case the diverticulum must be drained independently, and the operation for its removal performed as soon as possible after the lithotomy.

Relationship between Ureter and Diverticulum.

It is important for the operator to bear in mind the close relationship between the ureter and the neck of the diverticulum. In the first place, the orifices of the "lateral group" of diverticula are always found in a limited oval area of the bladder wall, which lies above and to the outer side of the corresponding ureteric orifice. Occasionally the ureter opens into the diverticulum itself, in which case its orifice lies just within the lower and internal quadrant of the mouth of the sac. Outside the bladder the relationship is even more intimate. If the ureter is traced upwards from the point where it enters the bladder wall, it will be found to lie at first immediately below the lowest point of the neck of the sac. It then passes backwards and upwards behind it. This means that it follows the curve of the lower and posterior quadrant of the opening. If the ureter is traced still further upwards, it will be found to lie either in the cleft between the bladder and diverticulum, or to occupy a deep groove in the posterior wall of the latter. If the diverticulum stands well away from the bladder, the ureter lies between the two, but if it is in close contact with the bladder wall, and especially if it lies partly behind the bladder, the ureter occupies a deep sulcus in its posterior wall. In either case the ureter is compressed or displaced by the drag of the sac, and dilatation of its upper part and of the corresponding renal pelvis has frequently been observed. In eight of my cases the ureter was exposed during operation, and on each occasion it was found either to be dilated or thickened. If the ureter opens into the diverticulum itself it usually tunnels through the lower and posterior quadrant of the neck. This is simply an exaggeration of the usual relationship. The proximity of the ureter to the diverticular orifice must be borne in mind whenever the condition is treated by splitting down the partition between the sac and the bladder. Such an incision should not be made directly towards the internal meatus, but should be curved forwards a sufficient distance to avoid any chance of injury to the ureter.

Residual Urine.

Perhaps one of the most remarkable phenomena connected with vesical diverticula is the large amount of urinary obstruction they cause. In fact, obstruction and infection are the most usual indications for operation. The amount of residual urine is usually measured by passing a cathether immediately after the patient has emptied his bladder as completely as possible by micturition, but in some cases, especially if the diverticulum is large, it is impossible to drain off all the urine by this means. The amount left behind is often considerable, and may for convenience be called the "concealed residual." I first suspected the presence of this concealed residual in Case 2. At the operation the bladder was washed out and emptied as completely as possible, and then filled with air, yet when it was opened the diverticulum was full of lotion. The presence of this concealed residual was also demonstrated by means of the cystograms taken in Cases 12 and 13. In both these cases the first cystogram was taken when the bladder was filled to repletion. (Fig. 5 on Plate.) It was then emptied as completely as possible by means of a catheter and the second exposure made. In both cases the diverticulum remained full, and in addition there was a distinct shadow due to the presence of a certain amount of opaque fluid in the bladder itself. (Fig. 6 on Plate.) Although it is easy to demonstrate the presence of this concealed residual I do not know of any means of accurately estimating its amount. This concealed residual is of great practical importance as it renders all attempts to estimate the functional cativity of the kidneys, by means of tests applied to the bladder urine, fallacious. This applies both to the elimination of dyes and to the urea-concentration test, and if these methods are made use of the urine should be obtained directly from the kidneys by means of ureteric catheterisation. For example, in Case 12 the urea-concentration test carried out on bladder urine gave only 1·4 per cent., while the same test carried out on urine obtained by catheterisation of both ureters gave 3 per cent. of urea from each kidney. The latter was the true estimation of the renal function; in the first case the urine was diluted with lotion which could not be evacuated from the bladder by means of the catheter. If it is impossible to catheterise the ureters, one must depend on an estimation of the blood-urea.

Diagnosis.

In the majority of cases the diagnosis of the presence of a diverticulum is made by means of the cystoscope. The appearance of the orifice of a large sac is so characteristic that it is impossible not to recognise it at a glance. (Fig. 8 on Plate.) Occasionally, however, cystoscopy is rendered difficult on account of intense cystitis, or the orifice may be hidden by bullous œdema or a growth, or if the bladder has not been fully distended it may lie between two folds of mucous membrane. In these cases a cystogram should be made. The diagnosis of the size and relationship of the diverticulum can be made by means of cystograms, but to obtain the best results the technique must be carefully thought out. I now use a solution of sodium iodide which has been boiled and allowed to cool to the body temperature. The strength of the solution depends on the capacity of the bladder, which should be estimated beforehand. If it is less than 10 oz., I use a 15 per cent. solution, if it lies between 10 and 20 oz. a 10 per cent. solution is best, while if the capacity is more than 20 oz. a 5 per cent. solution is quite sufficient. If too strong a solution is used the shadow is so dense that it is difficult to distinguish between the shadow thrown by the diverticulum and that thrown by the bladder. In Fig. 5 (on Plate) a 30 per cent. solution was used, but the shadow was much too dense, and there was practically no differentiation between the bladder and diverticulum. As a general rule, the weakest opaque solution that will give a satisfactory shadow is the best one to use. When the patient is on the X-ray couch a catheter should be passed and the contents of the bladder evacuated as completely as possible. The opaque solution should then be run in, either by means of a syringe or by gravity, until the patient experiences a desire to micturate. A spigot is then placed in the catheter and a radiogram taken in the antero-posterior position. The patient is then rolled over on his side until the shadow of the diverticulum is distinct from that of the bladder. The best position is easily determined by means of the fluorescent screen. If the diverticular opening is in the posterior part of the bladder, as it nearly always is, the patient should be rolled to the opposite side. A second exposure should be made in this position. Lastly, without altering the patient's position, the spigot should be removed from the catheter and the bladder emptied as completely as possible. A third exposure should then be made. This is to ascertain if there is any concealed residual urine.

Conclusions.

(1) Excision of the sac is the only rational treatment of vesical diverticula.

(2) No single set operation is suitable for all cases.

(3) If the case is complicated by prostatic or urethral obstruction both conditions should be treated at the same sitting. When this course is not feasible it is better to remove the diverticulum first, and treat the obstruction at a later sitting.

(4) A preliminary cystotomy does more harm than good in most cases.

(5) The presence of a calculus either in the bladder or in the sac is an indication for excision of the diverticulum.

(6) As a rule the ureter lies in close relationship with the neck of the sac, and must be guarded from injury during operation.

(7) The contents of a diverticulum cannot always be evacuated by catheterisation. The urine left behind after catheterisation, often a considerable amount, I have termed the "concealed residual."

(8) The presence of concealed residual urine vitiates all tests of the renal efficiency which are carried out on bladder urine. To obtain an accurate estimate of the renal function it is necessary either to catheterise the ureters or to trust to an estimation of the blood-urea.

(9) The presence of a diverticulum is best diagnosed by means of the cystoscope, and its size and position ascertained by means of cystograms.

Faculté de Médecine de Paris.—A post-graduate course in Dermatology and Venereal Diseases, under the direction of Prof. Jeanselme, will be held in the clinic of dermatology and syphilography, Hôpital Saint-Louis, and in the clinic amphitheatre (Salle Henri IV.) at 40, Rue Bichat, beginning on Oct. 5th (dermatology) and Nov. 14th (venereal diseases). Prof. Jeanselme will be assisted by Profs. Sebileau and Gougerot, and Drs. Hudelo, Milian, Ravaut, Lortat-Jacob, Louste, Lian, Darre, Tixier, De Jong, Sezary, Touraine, Coutela, Hautant, Lemaitre, Sabouraud, P. Chevalier, Burnier, M. Bloch, Hufnagel, Schulmann, Pomaret, Giraudeau, M. See, Bizard, Noire, Civatte, Ferrand, and Barbe. The fee for the course is Fr.150, and a certificate will be issued at its termination. Full particulars will be supplied on application to Dr. Burnier, Chef de Clinique à la Faculté, Pavillon Bazin, Hôpital Saint-Louis.

SOME OBSERVATIONS ON STRIÆ DISTENSÆ.

By F. BEDO HOBBS, M.B., B.Ch. Camb., D.P.H.,
RESIDENT MEDICAL OFFICER, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK, E.

(With Illustration on Special Plate.)

Striæ distensæ, which are also called striæ atrophicæ although there is no histological evidence of a true atrophic condition, have been reported at various times in medical literature. These cutaneous changes were first observed on the extremities by Ascherson [1] in 1835, and between 1856 and 1863 Reuss,[2] Röser,[3] and Förster[4] reported cases in association with typhus, typhlitis, and dysentery. Köbner[5] states that in 1867 Auerbach told him of a case of a 15-year-old boy with striæ on the thorax. This appears to be the first recorded case in this situation. Since then the striæ have also been noticed in other parts of the body and many and diverse views as to their origin have been adduced.

The condition is generally stated to be rather rare, and the figures of observers who have had the opportunity of examining a large number of cases certainly tend to confirm this. Thus Kaiser,[6] referring to typhus, says among 1932 patients suffering from this disease he found 25 with striæ over the patella. Again, Warnecke[7] found 12 patients with striæ distensæ on the thorax among 2000 male cases of pulmonary tuberculosis, while among 4000 women and girls with the same disease not a single case was observed. Kai Hammer[8] also found 12 cases—10 males and 2 females—among 5800 patients treated at Boserup Sanatorium. It is, however, probable that these changes are not so rare as is commonly supposed—the fact that their onset is insidious and painless probably accounting for the fact that they seldom attract attention. In the course of the last six months I have seen ten cases of striæ distensæ of the thorax associated with various diseases, and in considering these I hope to disprove some of the theories put forward regarding the causation of the condition, and confirm and amplify others, emphasising the point that they are neither a separate clinical entity nor in any way the manifestation of one disease, but are merely the result of the association of certain clinical conditions occurring in the course of many diseases.

Position and Appearance of Striæ.

Striæ distensæ have been reported in association with typhoid, typhus, colitis, scarlet fever, mumps, rheumatic fever, cerebro-spinal fever, pleurisy, pneumonia, pulmonary tuberculosis, intestinal tuberculosis, malignant disease of the pleura and peritoneum, septicæmia, and as a result of trauma. In addition to these I have also observed them in cases of infective endocarditis, nephritis, and in one patient with an abscess of the liver. Striæ may be found in the neighbourhood of the anterior axillary fold, over the breasts, abdomen, buttocks, thighs, and above the patellæ. There is some evidence that they may occur in these situations in quite healthy individuals, but when associated with disease the postero-lateral portion of the thorax, about the level of the eighth to twelfth dorsal vertebræ, appears to be the commonest situation. The skin changes may be unilateral or bilateral; in the latter case they are usually more marked on one or other side.

When they first occur the striæ are purplish in colour and appear as a series of irregular livid streaks, in which, in a few instances, small hæmorrhages are seen. The colour gradually changes to a dusky mauve and after some months fades altogether, taking on the pearly-white appearance of scar-tissue. The striæ are depressed below the level of the surrounding skin, as can easily be felt by running the finger across them, but some, in the later stages, of which Case 7 was an instance, take on a keloid appearance and are raised in the form of wheals. The lines are as a rule rather irregular in outline and vary from ½ in. to 8 in. in length with an average width of about ⅛ in., although in one of my cases a recently formed stria was ⅝ in. in width. On the back these lines are horizontal, while on the front of the abdomen they are vertical, tending to run obliquely outwards and downwards as they occur nearer the flanks. On the thighs and over the axillæ they are also more or less vertical, but are horizontal when found above the patellæ; that is, in all situations the long axis of the striæ is perpendicular to the direction in which the maximum tension which seems to have caused them is exerted. In the majority of cases the onset is insidious, and the striæ are not noticed by the patients until their attention is directed to them by the doctor or nurse.

Sir Dyce Duckworth[9] reported a case with striæ distensæ over the outer side of one thigh in which there was a marked degree of hyperæsthesia in the affected area. One of my patients, Case 7, also complained of soreness around some of the newly-formed striæ, but none of the other patients had noticed the presence of their striæ. Freund[10] and Craven Moore[11] have reported cases in which there was some blunting of sensation over the striæ, but in the vast majority of cases no sensory changes are found.

The striæ appear to occur only in young adults, the ages of my ten cases being within the narrow limits of 15 to 18 with one exception, who was aged 24. The age period of practically all the cases to which I have referred in the literature also lay between 12 and 22, 80 per cent. of these being between 15 and 20. One of Warnecke's patients was aged 49 but had been ill for 26 years, and there was no note as to when the striæ had first appeared. This restricted age-incidence alone ought surely to throw some light on the ætiology of striæ distensæ. There seems to be some difference of opinion regarding the sex-incidence. Cramer,[12] Warnecke,[7] and Hammer[8] have found a great preponderance among the male sex, while Schultz[13] and Riecke[14] report the reverse. In my ten cases the sexes are equally divided.

The following is a brief history, together with a short description of the striæ distensæ found in ten cases:—

CASE 1.—Female, aged 18, well nourished, with fairly advanced tuberculosis of both lungs of one year's duration. Confined to bed since May, 1922. Irregular evening rise of temperature throughout. Well-defined purple striæ distensæ in lower dorsal region on both sides—more marked on right. These were first noticed in January, 1923, but had probably been there some time. A few striæ actually over the vertebræ. Always lies on her back. Lost 12 lb. in last nine months.

CASE 2.—Female, aged 16, emaciated, with extensive tuberculous disease of left lung and early disease right side, three months' duration. Evening temperature of 101° to 102° F. A few recently formed striæ on postero-lateral portion of right side in lower dorsal region. Lies on right side.

CASE 3.—Male, aged 17, fairly well nourished, with extensive tuberculous disease of right lung, of 14 months' duration. Artificial pneumothorax induced on right side, July, 1922, followed two and a half months later by pleural effusion. Pyrexia during first few months, which later disappeared, except for an occasional rise. Well-defined striæ distensæ on both sides of back from ninth dorsal to first sacral vertebræ (see photograph). These appeared early in September before pleural effusion appeared. Usually lies on his back, occasionally on his right side. Gained 2 lb. in eight months.

CASE 4.—Male, aged 17, poor nutrition, rather toxic, and myoidema present. Tuberculous infiltration of both upper lobes and also larynx, six weeks' duration. Average evening temperature 99·6° F. Faintly marked striæ over right lower ribs in lower dorsal postero-lateral region. A few also over posterior folds of axillæ. Always lies on right side. Gained 11 lb. in last six weeks.

CASE 5.—Male, aged 15, poor nutrition, with pleural effusion of left side, which gradually resolved over period of three months. Irregular evening temperature for first month. A few purplish striæ in lower dorsal region left side. Lies on left side. Gained 19 lb. in three months.

CASE 6.—Male, aged 15, with advanced rheumatic endocarditis. Ascites and œdema of legs on admission which rapidly disappeared. Large liver and spleen. Confined to bed three months. Slight pyrexia occasionally. Striæ distensæ of recent origin noticed in right lower dorsal region in February, 1923—i.e., three months after admission. Usually lies on back, but frequently on right side.

CASE 7.—Female, aged 18, rather fat, with morbus cordis of rheumatic origin, auricular fibrillation, and recent infective endocarditis. In hospital for six months in 1921, when striæ developed in right lower dorsal region. By 1923 these had become very deep pearly-white scars running more or less parallel with the lower dorsal ribs. Below these on the right flank were very prominent raised striæ passing obliquely upwards and forwards from the posterior part of the iliac crest towards the abdomen, ending in the nipple line. These were almost keloid in appearance, and were called striæ hypertrophicæ. In the left lower dorsal region and over the delto-pectoral triangles and the front of the abdomen were more recent scars of a livid hue. These were transverse over the back and more or less vertical over the arms and middle of abdomen, becoming more oblique as they approached the flanks. The liver was enlarged and tender, and there was some ascites. Two days before death patient complained of a well-marked, tender, recently formed stria present in each iliac fossa. During her previous illness in 1921, patient stated she used to lie on her right side; recently she remained almost entirely on her back.

CASE 8.—Female, aged 15, with mitral stenosis following two attacks of rheumatic fever. Confined to bed entirely for two months, and then got up gradually. Pyrexia for first fortnight. Striæ distensæ in lower dorsal region on both sides and in mid-line of back appeared about two months after admission to hospital. Always lies on back. Gained 6 lb. in four months.

CASE 9.—Male, aged 21, with parenchymatous nephritis of three months' duration, associated with œdema of thighs and lumbar region. Recently formed purplish striæ in lower dorsal region on both sides and also on thighs. Irregular evening temperature throughout illness. Always lies on back.

CASE 10.—Female, aged 24, with large liver abscess, secondary to small localised appendix abscess. Consolidation of right lower lobe. Very large liver. Duration of illness two months. Marked pyrexia and toxic symptoms throughout. Very marked lineæ distensæ over lower dorsal region almost entirely on right side, noticed about six weeks after onset. Lies on back.

Ætiology.

It appears that in some cases the striæ occur as a direct result of distension from within, caused by subcutaneous œdema, or pleural and peritoneal effusions. I have recently seen striæ over the dorsum of both feet in a girl aged 12 suffering from pronounced cardiac œdema, and conclude that a simple distension of a badly nourished skin was the cause of their appearance. The striæ on the thighs of Case 9 were probably produced in the same way.

They are, however, often found in the absence of any sort of effusion, and can then be classified according to the anatomical position which they occupy: 1. Striæ found in the neighbourhood of the anterior axillary fold, and on the breasts, abdomen, thighs, and buttocks. In all these situations there is a tendency for fat to accumulate. 2. Striæ found in the lower thoracic region and above the patellæ. In these situations there is very little tendency for fat to accumulate, and the effect of position seems a much more potent factor. In both cases the underlying features of production are the same. Kai Hammer[8] has reported a series of 12 tuberculous cases, all of which fall into the first group described above, and concludes that they are due to distension of the skin caused by the rapid accumulation of fat in the subcutaneous tissues.

I have recently seen two cases which support this view. One was a girl, aged 20, in perfect health, who had gained 1 stone in nine weeks, and whose thighs had increased 1 in. in circumference. She consulted me because she had noticed some livid mauve lines running vertically on the inner and outer sides of both thighs. On examination these were found to be well-defined striæ distensæ. The other case was a young man who, during convalescence after an empyema, had gained 1 stone in 12 weeks, and had developed striæ over both deltoids and above the anterior axillary fold. He stated that his chest measurement had increased to such an extent that his coat and waistcoat, which had previously been loose, now felt extremely tight and uncomfortable.

It seems that there is one group of cases at the adolescent period characterised by striæ in situations where large deposits of fat are rapidly laid down. In this group the growth of the skin is unable to keep pace with that of the subcutaneous tissues and the striæ occur as a result of this rapid distension. Hammer's conclusion that the striæ of pulmonary tuberculosis are directly due to a gain of weight appears unwarranted when their occurrence in other situations such as the thorax is considered. Among my ten cases of thoracic striæ only two showed any appreciable gain in weight. The comparative frequency with which the striæ have been found in typhoid and other prolonged diseases in which there is a tendency to lose flesh also does not seem to support Hammer's theory. Other observers have taken the opposite view—namely, that the striæ are the result of emaciation and malnutrition, a theory for which, per se, there also appears to be very little evidence.

A neurogenic origin has been suggested by several people, but no conclusive evidence for this has been produced, and it is impossible in the majority of cases to correlate the situation of the striæ with the disease from which the patient is suffering. Striæ distensæ are frequently found on the side opposite to that of the lung lesion, which fact, together with the absence of any pain, is difficult to explain on the basis of a neurogenic origin. Similarly there is no evidence to support the theory that there is a trophic influence at work on the skin. If this were the case why are the striæ usually so localised, and why are there no obvious sensory or vaso-motor changes? It is possible that minute hæmorrhages or thromboses may occur in the skin and play a part in the production of the striæ. The section of one of my cases examined microscopically certainly shows many points of hæmorrhage into the dermis.

The effect of posture, however, seems much more important, a point on which Parkes Weber [15] has already laid emphasis. In those patients who generally lie on the back the striæ were found on both sides of the mid-line, although it was noticed that there was a tendency for them to be more marked on the right side, possibly from the fact that the majority of people lie more on the right side than on the left. The position and weight of the liver may also affect this. Where the striæ were confined to one side I found on inquiry that without exception the side affected was the one on which they were accustomed to lie or had lain during their illness. In those patients who are in the habit of lying on their backs and who while in bed adopt a semi-reclining position with their shoulders propped by pillows, the lines are found in the lower dorsal region, which is the position of greatest convexity, where the skin is maintained at its greatest tension. Similarly, in a person who lies on one side, the point of maximum convexity is in the region of the postero-lateral portion of the lower part of the thorax where the striæ are commonly found. In the same way, transverse striæ are produced above the patellæ in patients who lie in bed with their knees drawn up, particularly in abdominal conditions such as typhoid. In cases of pleural effusion one may expect to find striæ distensæ on the homo-lateral side. In pulmonary tuberculosis, however, when the lesion is more or less one-sided, the striæ are found on the contra-lateral side. This is due to the fact that patients with unilateral pulmonary tuberculosis nearly always lie on the unaffected side.

Cramer [12] described seven cases of more or less unilateral pulmonary tuberculosis, in all of which the striæ were found on the contra-lateral side. This was ascribed by him to the compensatory distension of the chest on the healthy side, but although there is no record as to which side they lay on, it seems probable, in view of the nature of the disease, that it was on the healthy one, on which side the striæ appeared. All my cases were confined to bed for long periods, the shortest being six weeks, during which time the majority of them had well marked and continued pyrexia. This is not regarded as an essential factor in the production of the striæ, particularly as they have been found to occur in the absence of any fever, but it is merely a manifestation of the toxæmia of varying degree which appears to be a common factor in the debilitating diseases with which these cutaneous changes are frequently associated.

The narrow age-limit leads one to suppose that the skin at this period is much more susceptible to such changes. From 15 to 20 is the age when great structural alterations in the body, particularly the skin, are taking place, and if the nutrition is at all impaired by any toxic condition or prolonged disease, the skin being very delicate, the elastic fibres are more easily ruptured when subjected to any strain. This condition is somewhat analogous to rickets, where within a definite age-period, bony changes occur as a result of deficient nutrition.

Relation of Striæ Distensæ to Lineæ Gravidarum.

An interesting point is the relation of these striæ distensæ to lineæ gravidarum. Is the mode of origin the same in the two cases? Some observers are inclined to think that it is, but although there is some similarity it seems probable that the two conditions are not identical. Lineæ gravidarum are found at any age during which pregnancy occurs, while the age-period is very strictly limited in the case of striæ distensæ. There is also a difference in colour. The striæ gravidarum are pinkish-white in appearance even when first formed and never present the livid purple colour of striæ distensæ, which seems to indicate a more profound change. One might argue that the general nutrition of the body, including the skin, is lowered during pregnancy, and that the pressure of tight clothing on the distended abdomen acts in the same way as the pressure produced by lying in one position. A comparison of the microscopical appearances in the two conditions should throw some light on the question, but I have unfortunately not had the opportunity of doing this.

Microscopical Appearances.

In only one instance (Case 7) have I been able to obtain sections of the striæ for microscopical examination. These, together with control sections of normal skin, were stained by the Pianese method, and also by a combination of Van Gieson's and Weigert's stain, which demonstrated the elastic fibres very clearly. The epidermis showed no appreciable difference as compared with the normal skin, but well-defined changes were observed in the cutis vera. The connective tissue bundles appeared to be more spread out and parallel than in the normal, but the most noticeable change was in the elastic fibres, which were broken up into small strands and scattered irregularly over and around the connective tissue bundles instead of being intimately intertwined among them. In the centre of the stria the elastic fibres seemed to have disappeared entirely, but their retracted stumps were found lying curled up in little bundles on either side. Sections of the hypertrophic striæ from the same patient showed a great increase of connective tissue layer, scattered through which were a great number of blood-vessels. In these sections there appeared to be very little elastic tissue, and what there was was confined to the periphery of the scar.

Conclusions.

The conclusions at which I have arrived are:—

1. That striæ distensæ are confined almost entirely to young adults between the ages of 12 and 22.
2. That at this age the skin is very delicate and growing rapidly, and that the elastic tissue fibres rupture allowing the white fibrous tissue and overlying epidermis to stretch, giving rise to striæ distensæ.
3. That striæ distensæ may be associated with almost any febrile illness.
4. That the distension and ultimate cleavage of the skin may be caused in healthy individuals by the rapid accumulation of fat in the subcutaneous tissues of the axillæ, thighs, &c.
5. That in other cases it is due to a simple distension following an effusion into the subcutaneous tissues.

6. But that often the nutrition of the skin is impaired by some constitutional disease, and that the main factor in these cases is the effect of posture—the striæ occurring at the position of maximum tension.

Finally, I wish to express my thanks to the physicians of the Victoria Park (Chest) Hospital for their courtesy in allowing me to publish these notes of the cases under their care, and to Mr. A. W. Smart, of the Pathological Department, for preparing and staining the skin sections.

HOME DISINFECTION AND THE CONTROL OF SCARLET FEVER.

BY K. SIMPSON, M.D. EDIN.,
M.R.C.P. LOND., D.P.H.,
DEPUTY MEDICAL OFFICER OF HEALTH, COUNTY BOROUGH OF CROYDON.

THE following remarks regarding scarlet fever and home disinfection apply to that disease, neither as representative of infectious diseases as a whole, nor, generally speaking, to the practical sanitary measures necessary in all cases for their prevention. It would be quite fallacious, for instance, to suggest that tuberculosis—a disease differing widely from scarlet fever both ætiologically and epidemiologically, although possessing the common feature of infectivity—could be controlled similarly to scarlet fever from the preventive standpoint.

The chart, which is taken from the annual report of the medical officer of health, Croydon, for 1922—in great measure a replica of that produced the previous year—shows clearly that the most important factor in the spread of scarlet fever is school attendance, the disease waxing or waning according as the public elementary schools of the borough were open or closed during the year, allowance being made for the pre-school period of life which always accounts for a considerable number of cases. Although milk supplies, laundries, domestic animals, &c., have all been credited in the past, and probably not without some good reason, with furthering the spread of scarlet fever, the fact remains that the disease is one, in the great majority of instances, affecting school life and the pre-school period, and that by far the most important agent in its spread is school attendance, although in a minority of instances other factors, such as those mentioned, do from time to time play a certain part, although even in them a missed case or a carrier is, in all probability, the primary focus of dissemination.

Spread of Scarlet Fever.

Scarlet fever is spread by actual cases of the disease, carriers, and to a less extent by fomites, provided sufficient pabulum for an outbreak—general or sporadic—is available in susceptibles, that immunity which is known to exist during the first year of life becoming in many cases exhausted in succeeding years. Actual cases of scarlet fever may be recognised or not, the latter group including mild cases confused with rubella, and others which may have been missed altogether. Definite cases, generally speaking, explain the spread among home susceptibles, see table, column C, where the primary case is nursed at home, whilst mild ambulant and missed cases are responsible for a certain percentage of those spread by school attendance, the majority of school infections being, in all probability, due to the carrier. Carriers in scarlet fever, as in other similar infections, are of two types—the direct and the indirect—and in some 50 per cent. of cases may exhibit certain obvious clinical symptoms associated with the carrier state. The direct carrier has previously suffered from the disease, whilst the indirect carrier, so far as is known, has not. Direct carriers include those also who, after return from home or hospital isolation, have given rise to "return" cases. Carriers, therefore, in many instances may attend school from homes which have been previously disinfected to the satisfaction of the sanitary authority, and may also presumably come from homes where there has been no previous suspicion of infection. Parenthetically the value of home disinfection can, even at this juncture, be seen to be almost nil in so far as the danger to be apprehended from the carrier is concerned, who after the customary period of isolation has returned to school, disinfection meanwhile of the home playing no part in any lessened tendency to further spread of infection through the medium of school attendance and carriers, or the further infection of home susceptibles by carriers before resuming school. Fomites include all infected or presumably infected articles in a home where a case of infectious disease is known to have occurred.

Home Disinfection.

Disinfection, as at present carried out by most sanitary authorities, briefly consists in spraying infected rooms and fomites with either a weak solution of izal or formalin, or generating sulphur dioxide by burning sulphur candles on the premises (besides certain other less commonly practised methods occasionally made use of) after the patient's removal to hospital, or where the case has been nursed at home, after the return of the case from isolation. At the same time the clothing and bedding of the patient are usually removed and disinfected by the sanitary authority—in my opinion the only useful part of the procedure. In the table will be found certain particulars relating to the incidence of scarlet fever during the years 1921 and 1922 in Croydon, excluding for reasons of comparison all cases occurring at institutions during the period. Col. A deals with all cases removed to hospital and where the home was disinfected within 48 hours. Col. B deals with cases nursed partly at home and partly in hospital during an epidemic period extending from the beginning of

Table giving Particulars Relating to Scarlet Fever Cases Notified during the Years 1921 and 1922, but excluding all Cases occurring at Institutions in the Borough of Croydon.

Col. A.—Hospital cases removed within 48 hours.

Col. B.—Home cases and hospital cases (nursed more or less at home and hospital—epidemic period).

Col. C.—Home cases, including a small number not removed during epidemic period.

—	A.	B.	C.
Number of cases notified	972	254	239
Number of "susceptibles" under 15 years of age in infected houses at onset of illness of primary case ..	1148	301	155
Number of secondary cases occurring from onset of primary case. (1) During first seven days ..	85	13	17
Percentage to susceptibles	(7·49)	(4·31)	(10·96)
"Incidental" infections—i.e., (2) after seven days and prior to the primary case leaving isolation or before return from hospital ..	50	20	18
Percentage to susceptibles	(4·35)	(6·64)	(11·61)
(3) "Return" infections	35	1	1
Percentage to susceptibles	(3·1)	(0·33)	(0·64)
Total of "incidental" and "return" infections	85	21	19
Percentage of this total to "susceptibles"	7·3	6·9	12·2

November, 1921, to the end of April, 1922, when the isolation hospital was over-full. These latter cases were removed as and when hospital accommodation could be found, the usual home disinfection being subsequently carried out. Col. C deals with home cases entirely. The percentage of secondary cases to susceptibles is greatest among home cases—obviously due to direct infection from the primary case—both during the first seven days after occurrence, 10·96 to 7·49 and 4·31, and subsequently ("incidental" infections), but prior to the return of the original case from isolation, being 11·61 in home cases compared with 4·35 and 6·64 respectively in the others.

With regard to hospital cases which were removed and the home disinfected within 48 hours, the infective influence of the primary case may not have been altogether effaced before the end of the first week, but subsequently to that period and disinfection the primary case can presumably hardly be expected to have exerted any influence at all upon the occurrence of subsequent cases. Disinfection and hospital isolation, therefore, fall considerably short of preventing secondary cases amongst susceptibles in homes where primary cases have occurred, whilst we see from the chart that the disease is spread in the great majority of instances through missed or carrier cases attending school or carriers of pre-school or school age at home, factors over which home disinfection exerts no control, even assuming for purposes of argument that such disinfection has been accurately and effectively carried out. (Other facts borne out by the table, such as the superiority of hospital over home isolation, and the greater proclivity for hospital cases to account for "return" cases, does not concern the further trend of this article.)

If fomites and infected houses, rather than carriers and mild cases, are to be credited with the spread of scarlet fever generally, it is obvious how almost useless the practice of disinfection has been, almost amounting to a confession of failure hitherto to prevent the further incidence of dissemination of infection, whether we consider the incidence of home or school cases.

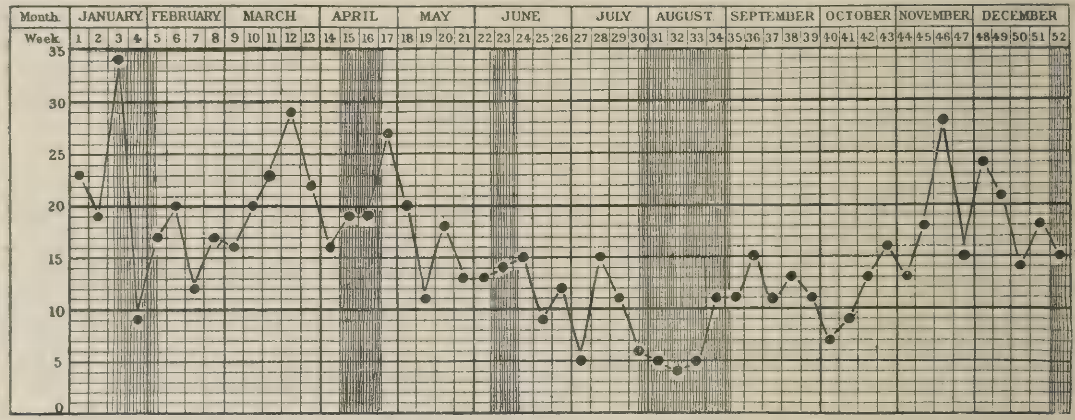
Carriers of the Disease.

How, it may be asked, is scarlet fever perpetuated, and how is the outbreak initiated? The answer, I believe, is in both instances, through the recent or chronic carrier, the former instrumental in acute outbreaks, while the latter, mainly recruited from the former, is concerned with the appearance of sporadic cases and the initiation of actual outbreaks. A defect in the chain of sequence is, however, created through our still incomplete knowledge of the bacteriology of this disease. Whether or not the particular causative streptococcus described represents more than a symbiotic combination conditioned by the pathological states present in the sufferer or carrier and analogous to the association of Hofmann's bacillus with the throat in diphtheria, we have yet to learn.

A carrier probably possesses two requisites—a particularly low bactericidal power for some specific micro-organism, and an abnormal or pathological condition of the naso-pharynx suitable in the case of scarlet fever either for its parasitic endurance, or more probably some resting phase of its existence. On the other hand, the condition present—pathological or otherwise—may be such that the parasite cannot effectively be dealt with by the anti-parasitic powers of the host. An actual outbreak of scarlet fever is, so far as we can tell, dependent upon a degree of overcrowding either at home or in school during the presence of certain meteorological conditions met with in England, more particularly during the last quarter of the year, and presumably absent in some tropical parts where the disease has not yet appeared. When cases of scarlet fever begin to appear, can the disease be, in any particular, further prevented by disinfection after the primary case has been removed to hospital? I think not with any degree of success, because, as I have already attempted to show, the disease is mainly, if not entirely, spread by carriers and mild or missed cases both at home and through school attendance, and secondly because home disinfection cannot in any sense of the word be regarded as complete and satisfactory. Complete disinfection of an infected room cannot, for example, be satisfactorily carried out in the many one-roomed tenements met with in any of our large towns, unless all the contacts could be removed from their surroundings for some 24 to 36 hours. The clothing of the contacts again—in many cases the only clothing possessed—cannot practically be dealt with as regards satisfactory disinfection, assuming that contacts are infectious through their clothing, a point which I am not prepared, to any extent, to admit.

To summarise the question of home disinfection, therefore, it will be admitted that at best it is little more than a formal, much less than a complete proceeding, and consequently can neither reasonably prevent subsequent infection occurring in an already apparently disinfected home amongst susceptibles—susceptibles of school age being meanwhile excluded from school—nor the subsequent spread of the disease once an outbreak has occurred which is, as already suggested, almost entirely dependent on carriers and school attendance, rather than fomites, leaving out of account for the present sporadic cases met with from time to time in the adult. I am strongly of opinion that much of the funds at present spent upon disinfection could be more usefully employed in creating a healthier state of the naso-pharynx of the school-child by directing greater precision to the examination and

Chart Showing Weekly Notifications of Scarlet Fever, 1922.



The shaded portions represent periods during which the schools were closed.

treatment of all such defects discovered upon routine medical inspection of school-children, by preventing overcrowding in schools, and by the prompt closure of all schools or school departments—public, private, and Sunday—in any area threatened with an outbreak of scarlet fever. By these measures can it be hoped, in the future, to more surely approach the eradication of such a scourge of young life as scarlet fever is, rather than by further pursuit of the phantom of home disinfection, at best but an incompletely carried out procedure justifying neither the time nor the money spent upon its performance.

So far as home disinfection is required after the patient's removal, blankets, &c., from the home used in conveying him or her to hospital should, as a matter of course, be disinfected before their return, whilst the further disinfection of the home need only, in my opinion, be directed to an effort on the part of the occupants to spring-cleaning their infected room or apartments by the application of the less extravagant if not equally efficacious disinfectant properties ot sunlight, soap, and water. Such an arrangement, however, would not prevent householders who wished their premises disinfected after the orthodox manner from having the same carried out by the sanitary authority on the payment of an arranged fee.

The opportunity was taken at the outset of this article to emphasise the fact that remarks applicable in so apparently simple a matter as home disinfection after scarlet fever would not necessarily be true in respect of other infections belonging to a different category, such as tuberculosis. In closing, let it be similarly emphasised that the aim of this article has been not an attempted refutation of the principles of disinfection when rightly and appropriately used, but rather an analysis of the present inadequacy and inutility of home disinfection as a means of controlling the spread of scarlet fever.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT PORTSMOUTH.

(Continued from p. 362.)

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 25TH.

AT the opening session Dr. HENRY DEVINE (Portsmouth), the President, gave a short address in which he recorded the changed outlook of psychiatry which was coming to regard itself as a branch of general medicine. A discussion on

The Nervous Child

was opened by Dr. H. C. CAMERON (London), who said that he proposed to confine his remarks to two aspects of the wide subject which he had to talk about. He would describe certain peculiarities of physique and posture which were frequently found in the nervous child and would examine briefly the rôle played by parental management in provoking or controlling the disturbances of behaviour for which advice was sought. In most nervous children one was struck by the want of tone in the skeletal muscles. The trunk was not braced by the muscles at the back, the feet tended to be separated, and the shoulders carried far back, the abdomen being pushed forward, while the chest receded. The lack of tone in the shoulder muscles allowed the weight of the upper limbs to depress the points of the shoulders and so produced winged scapulæ. As a rule the small muscles of the face and hands were in constant movement, but in some of the worst cases the facial expression had been that of complete apathy. The posture and movements of the child were a good index of the state of the nervous system. Lack of tone was not confined to the skeletal muscles, but also involved those of the heart and blood-vessels, hence the pallor usually seen in these children. Albuminuria and cyanosis of the extremities were also common. Attacks of abdominal pain, and sometimes of vomiting, were generally due to emotional excitement or fatigue. The defect of posture sometimes led to enteroptosis. These children also were subject to frequent catarrhal infections, their lack of immunity probably being associated with the poor vaso-motor tone. Children of this type also tended to show abnormal temperature variations, giving a subnormal reading when exhausted, and showing variations above the normal when excited and flushed.

The study of the nervous child was to a great extent a study of his parents. In hospital little, on the whole, was seen of functional nervous disturbances because of the change of environment. At home the reaction of the child depended very largely on that of the mother. The young child was very prone to suggestion. Whatever was thought of him, said of him, even feared for him, that he was apt to become. Therefore, the symptoms of functional nervous disturbance among children were usually those about which the mind of the ordinary mother was most preoccupied. When a whole household was openly distressed by some abnormality of behaviour the child quickly caught the feeling and himself became anxious and apprehensive. This applied particularly to children who suffered from persistent anorexia or enuresis, whose mothers were usually found to be despondent and pessimistic. Timidity and foolhardiness likewise depended very largely upon the mother's attitude. Negativism in the child was usually found when there were frequent and repeated attempts at control with constant failure to achieve it. Children responded to the moods of their parents in a remarkable way. When the mother had lost her peace of mind, refusal to sleep, refusal of food, or refusal to go to school became formidable difficulties. Refusal of food was often the response of the restless child to the excessive urging of the mother. Amongst the poor one often encountered the opposite fault. Here the price of food being an important consideration, it was apt to be doled out grudgingly with comments upon the child's appetite, and the child responded to the stimulus by becoming a prodigious eater. Similarly, of eight cases which had been brought to him for insatiable thirst, only one had diabetes. In the other seven the demand for fluid grew as a result of the obvious reluctance with which it was conceded. He illustrated these points by means of several illuminating cases. Closely connected with the child's proneness to suggestion was his instinctive desire to assert himself and make himself the centre of the picture. To this end children might develop most extraordinary symptoms. He quoted instances in which the strangest abnormalities of behaviour proved to have their origin in a simple desire to create a sensation at any price. To understand the child, therefore, one must first understand the parent, and use the all-powerful influence proceeding from parent to child in the treatment of the disorder.

Dr. C. MACFIE CAMPBELL (Assoc. Prof. Psych., Johns Hopkins) remarked that Dr. Cameron had dealt in his paper mainly with the physical aspect of the nervous child. It was a fact that children of this type were often found to be suffering from some fundamental physical inferiority. It was in these cases that the psychiatrist looked for help from the physician. The psychopathologist was especially concerned with the problem of the child which was physically normal but presented abnormalities of behaviour such as pilfering, lying, and temper tantrums. It was important to realise a child as an individual personality with its own personal difficulties, and to appreciate that these might be of two kinds: Difficulty, on the one hand, of adapting to external situations; and, on the other hand, difficulty in the adjustment of the internal emotional forces to one another. Dr. Cameron had confined himself to the external difficulties, and the speaker found himself in complete agreement with what he had said about the importance of parental management. If the nervous child were to receive adequate treatment it was frequently necessary to get the parents to readjust their own scale of ethical values. He thought that on the whole people were ready to do this if they could be convinced that the health of their children depended upon it. In the case of the nervous child the psychiatrist was, as a rule, consulted for a symptom; he found it necessary to study the whole child and that led to a study of the whole home.

Dr. **HELEN BOYLE** (Hove) agreed with the President's contention that neurology and psychiatry should be considered as a single field for investigation. She was especially interested in the nervous stance which Dr. Cameron had described. She asked whether this was due to a constitutional physical defect, or whether it was simply the bodily expression of an emotional attitude—a disheartened stance. She thought on the whole it was the latter, and compared what she described as the war and post-war stance of adults as indicating the natural posture of a person suffering from fatigue and depression. She had analysed her own experience in the case of 40 children and had come to the conclusion that when a child compensated for its sense of inferiority its stance improved. This was so whether the compensation was a correct one from the social standpoint or not.

Dr. W. A. **POTTS** (Birmingham) thought that in some of these nervous children the trouble might be due to disturbance of the endocrine balance. He had known cases in which the administration of small doses of thyroid was followed by remarkable improvement. In other cases he thought the overgrown child might have exhausted its pituitary reserves, which might perhaps be restored by means of the administration of pituitary extract. He emphasised the importance of the parental attitude, not only in its direct influence on the child but indirectly through the example. Adaptational failure in the parent often led to similar failure in the child. With regard to treatment, he laid stress upon the importance of fresh air and of proper clothing. The parents' ideal in training the child should be to watch but not let the child know that it was being watched. He considered it most important that every child should have instruction both in some simple form of religion and also in the origin of life.

Dr. H. **CRICHTON MILLER** (London) regretted that Dr. Cameron had not gone more deeply into the question of ætiology of the amyotonia in these children. It was in matters such as this that the psychiatrist looked for help from the physician. He suggested that the cause might be a defect in the calcium metabolism associated perhaps with parathyroid deficiency. The problem child, however, was often physically fit. In the course of progressive adaptation the child depended to some extent upon the stimulus of social opinion. The only child, being sheltered from the world, lacked the stimulus to deal with its own difficulties. With regard to the treatment of delinquents, he pointed out that a child will often prefer to be punished as a criminal rather than be ignored as a mediocrity. In the treatment of many of these conditions it was most necessary to switch off the limelight. A common problem of childhood about which medical men were consulted was enuresis. This was the supreme example of the infantile state and was a symptom of failure of progressive adaptation. There was a danger lest the child who was threatened with the social consequences of this habit might develop a revenge motive towards society, in its desire to secure compensation for being treated as an outcast. Hence the association with enuresis of habits such as wilful stealing and lying.

Sir **ROBERT ARMSTRONG-JONES** (London) referred to the existence of a National Society for the Education of Parents which was doing good work. He maintained the importance of the maxim "Don't say 'Don't.'" One should reason with the child, and lead rather than force. In training, the principle of retributive justice should be adhered to. He considered that a full allowance of sleep was of the greatest importance to children. A child of the nervous type should get at least 12 hours nocturnal rest, if not sleep, up to the age of 15. He wondered whether some of the moral imbecility seen in later years was not a product of the nervous child badly handled. He emphasised the importance of teaching children harmony of movement.

Dr. R. G. **GORDON** (Bath) asked what lay behind the desire to attract, the negativism, and other trends of the nervous child. Was it a matter of predisposition? McDougall regarded certain instinctive dispositions as fundamental and considered character as formed by environmental influences acting upon these factors. In the nervous child one or more of these instinctive dispositions might be over-stressed. He brought forward evidence to show that despite McDougall's theory a given set of instinctive dispositions did not always lead to the development of the same quality of character. Nervousness in the child expressed a failure of integration. In view of Bianchi's work, this failure might be correlated with a failure of development of the frontal lobes. He thought that analytic methods in young children were not likely to be successful because the child was incapable of understanding the treatment.

Dr. G. F. **HARFORD** (London) referred to the importance of squint in relation to nervousness in children. He referred also to a resolution carried at the last annual meeting of the Section to the effect that instruction in psychopathology should be included as an essential part of the medical curriculum.

Mr. W. S. **INMAN** (Portsmouth) referred to the frequent association of squint with left-handedness, and the association of left-handedness with stammering. He thought that the left-handed child, who remained so, was often the successful rebel against parental endeavour to compel right-handedness; whereas the unsuccessful rebel frequently became a stammerer.

Dr. L. A. **PARRY** (Hove) thought the nervous child was far more common to-day than 15 or 20 years ago. Dr. Cameron had given instructions for treatment; how far could the general practitioner be expected to effect a cure along these lines? He thought the percentage of parents who could be influenced was very small. He agreed with Dr. Potts as to the necessity of religious instruction. He did not think it advisable to instruct children in sex matters.

Dr. **POTTS** explained, in reference to Dr. Parry's remarks, that he did not consider deliberate instruction in sex matters necessary or advisable, but thought that the child's questions upon this subject should be frankly answered.

Dr. S. D. **BHABHA** (London) said that in the experience of his practice in East London nervousness was rare amongst Jewish children notwithstanding popular belief to the contrary.

Dr. P. **MACDONALD** (York) referred to the importance of postural training in the treatment of nervous disorders.

Dr. F. G. **LAYTON** (Walsall) referred to the difficulty of treating the nervous child in the back streets where the environment of the nursery was lacking.

Dr. A. G. **WILKINS** (Stafford) pleaded for better school accommodation in the future. He favoured the plan of open-air schools wherever possible.

Dr. **CAMERON**, in reply, again emphasised the fact that the emotional attitude of the child depended upon the emotional attitude of the mother. With regard to the ætiology of the stance of the nervous child, he thought an important point was the tendency of the child to react to any kind of illness in certain ways at different phases of its life. In infancy the digestive system was usually upset; later on locomotion and posture were thrown out of gear, whether the illness was due to a chronic infection or to a disturbance of the emotional life. He had found that class training in physical exercises had a good effect upon the attitude of both mind and body of these children. The slum child should be treated through the mother. Once the mother's confidence in her own ability to handle the child satisfactorily had been re-established treatment was likely to be successful.

THURSDAY, JULY 26TH.

On the second day, Dr. C. M. HINDS HOWELL being in the chair, Dr. E. F. BUZZARD opened a discussion on the

Sequelæ of Encephalitis Lethargica.

Referring to the difficulty of distinguishing between the primary results and the sequelæ of the disease, he defined sequelæ for the purpose of discussion as (1) those disorders of function which appeared for the first time after the disease had spent itself, and (2) progressive alterations in defects of function which had been left as more or less permanent legacies of the disease. It was probable that our list of sequelæ, already long, would still be added to, for every function of the nervous system might be affected. Mental sequelæ were common, therefore it was a matter of practical importance to warn the relatives that even a slight attack was apt to leave the nervous system below par for many months or even years. Unless such a warning note was sounded, patients were apt to return to work before they were fit, sometimes with disastrous results. In the majority the mental symptoms did not amount to more than lack of energy, depression, and insomnia, but in some instances there occurred profound alterations in the personality. He quoted cases illustrating this point. Perhaps the worst cases of this type were seen amongst children.

Involuntary movements might occur in the acute phase of the illness or make their first appearance later. They varied from rhythmical twitchings of one or two muscles to more complicated movements involving a whole limb. Generally they did not interfere seriously with voluntary activities. He referred in detail to a case in which the involuntary movements had been extensive and severe. In this case the muscular contractions were regular and their frequency corresponded to the pulse-rate—about 72 to the minute. The general tendency was for these involuntary movements to disappear in the course of time. The Parkinsonian syndrome was one of the commonest sequelæ. It might develop early, gradually become less marked, and never progress. At the other extreme was a group of cases in which the disability steadily progressed. Respiratory disorders were not uncommon and were of great interest. Hiccough and vomiting were frequent complications, and might persist for months after the illness. Optic neuritis was not infrequently observed at the height of the disease. Foster Kennedy had drawn attention to its occasional occurrence as a late symptom in convalescence. Lethargy in some cases might be regarded as a sequela, and might occur in the form of periodic attacks with headache. The explanation was probably a mild degree of hydrocephalus.

As to the pathogenesis of sequelæ, he thought that the inflammatory changes in and around the vessels played a large part in their development. There were, however, certain other sequelæ which could hardly be attributed to vascular deficiencies. He regarded the lethargy of encephalitis as probably dependent upon mechanical interference with the drainage of cerebro-spinal fluid from the third and lateral ventricles. Possibly meningeal thickenings and loculated cysts might also account for certain of the sequelæ. We were still without any specific treatment for the disease. Perhaps some of the mental disabilities might be avoided by insisting upon an adequate convalescence. Tremor might perhaps be lessened by means of hyoscine. And in one case of Parkinsonian rigidity suppositories of belladonna had produced temporary improvement. Generally a combination of psychotherapy and physical re-education had to be the basis of treating the sequelæ.

Dr. G. RIDDOCH (London) remarked that Dr. Buzzard had confined himself to sequelæ of two kinds: permanent after-effects and subsequent results of the original illness. He proposed to deal with the subject of relapses which he believed occurred in some cases. He cited the instance of a woman who, five years after an original attack of encephalitis lethargica, which had left her with a residuary ptosis, had a definite recurrence with mental and physical symptoms. He also quoted statistics relating to cases followed up from the out-patient department at which he worked. Mental deterioration had occurred in more than half the cases, and of these a large number were among young people—children under the age of 6 being perhaps most frequently and most severely affected. He quoted instances in which outbursts of uncontrollable temper and signs of moral degradation had followed the illness. Character changes of this kind were not necessarily associated with intellectual deterioration. Cranial-nerve palsies formed a group of common sequelæ and appeared in three-fifths of the cases, the nerves most frequently affected being the third, fourth, and sixth. He had seen persistent tachycardia both in the original attacks and as a sequela; and also attacks of respiratory distress, one of which had ended fatally. Symptomatic paralysis agitans was very common in the majority of cases. It was progressive and it was often associated with cranial-nerve palsies. This syndrome was not necessarily accompanied by mental deterioration. In his experience, myoclonic movements tended to disappear if the patient did not die. Movements of the choreo-athetoid type tended to persist. Anæsthesia was a rare symptom, but pain a common sequela. In all cases he thought the prognosis must be very guarded, because the virus probably smouldered on in the tissues for some time and might flare up at any moment. In the treatment of the involuntary movements he had found hyoscine hydrobromide useful.

Dr. HINDS HOWELL referred to a series of 34 cases which had come under his personal observation in the acute stage of the disease. Of these six died and 11 made a complete recovery. Of the remainder, he had been able to follow up the majority, and had also studied a number of other cases who had first consulted him for the sequelæ of the disease. He referred to three cases which developed Parkinsonian symptoms in their original illness, but had eventually recovered completely. He thought that an accurate prognosis in the early stages was extremely difficult—if not impossible. Patients who developed the Parkinsonian syndrome early, together with ocular palsies, he thought on the whole did badly; and in general he thought a bad prognosis was justified in cases which showed signs of severe involvement of the mid-brain. Some of the Parkinsonian cases tended to become progressively worse. On the other hand, he had a patient with choreo-athetoid movements who was doing well. Personality changes, in his experience, were the commonest sequelæ, although none of his cases had needed certification. The chief symptoms were loss of emotional response and slowness of the intellectual processes. There might also be impulsive actions, and these might take a suicidal form. The mental symptoms did not tend to improve. In the Parkinsonian cases he had noticed that the tremor was much less than the rigidity, and was as a rule coarser than that of true paralysis agitans. The commonest ocular defects were loss of convergence and accommodation. Of sleep disturbances, that which he had seen most frequently was a reversal of the rhythm occurring in young children. He referred to several instances in which there had been disturbance of the respiratory rhythm. He had noticed that seborrhœic dermatitis, especially of the scalp and forehead, was exceedingly common in these patients. Amongst other symptoms he had noticed abnormal appetite and obesity following the disease. He had never seen optic neuritis, and had generally considered its presence a point against the diagnosis of encephalitis lethargica. He was therefore all the more interested in Dr. Buzzard's observations. He thought that the frequent occurrence of rigidity as the sequel of a disease which particularly affected the mid-brain was of great interest in relation to the work of the physiologists upon decerebrate rigidity.

Dr. A. Feiling (London) confined himself to two aspects of the sequelæ in this disease: the ocular palsies and the Parkinsonian syndrome. In the first group he had found pupillary changes, such as inequality, loss of convergence and paralysis of accommodation, of common occurrence. Paresis of the extrinsic muscles was also common, unilateral or bilateral ptosis being of greatest frequency. These cases might closely simulate myasthenia gravis, for in encephalitis lethargica, as in the other disease, remissions and relapses might occur. He quoted a case in which, after an attack of encephalitis in September, 1920, a patient continued to suffer from ocular palsies, varying from time to time and from muscle to muscle over a period of 26 months. The Parkinsonian syndrome was familiar to all neurologists as a common sequel which might appear early or late in the history of the illness. He would refer to one or two points which were of use in differentiating between this and the ordinary senile form of paralysis agitans: (1) Many cases of the post-encephalitic form occurred at an age when true paralysis agitans was unknown. (2) The characteristic tremor was often lacking in the post-encephalitic form, whereas rigidity was constant. (3) Fragmentary conditions of rigidity were more commonly seen in the post-encephalitic cases. (4) Sialorrhœa also occurred more frequently as a sequela of encephalitis lethargica. In the matter of prognosis he thought that those cases in which the Parkinsonian syndrome commenced slowly after a long latent interval carried a bad prognosis, and this was especially the case in young children.

Dr. D. McAlpine (London) presented the results of an examination of the brain in two fatal cases. In one he had found some changes in the globus pallidus in the shape of perivascular cuffing and hyaline changes in the vessels, but the main incidence of the disease was upon the mid-brain. Serial sections of this part showed perivascular cuffing and remarkable changes in the pigmented cells of the substantia nigra. The pigment had disappeared from the cells and was scattered about the section. In the second case he found hæmorrhage into the basal ganglia on the right side and calcification of several arterioles in the anterior half of the globus pallidus. There were inflammatory changes in the mid-brain, but the substantia nigra on both sides was normal. Both these cases during life had shown symptoms of paralysis agitans. Both had died with symptoms of respiratory failure, but no changes of importance were seen in the medulla. Dr. McAlpine showed on the screen lantern-slides illustrating these histological changes. He referred in some detail to the literature of the subject and to the minute changes in the walls of the vessels, which he thought began with a deposition of fatty droplets, going on later to calcification. He had found similar changes in the acute stage of the disease, and had not, so far, been able to find them in cases of other disease with the important exception of a case of senile paralysis agitans.

Dr. C. P. Symonds (London) emphasised the fact that the severity of the sequelæ bore no constant relation to that of the original illness. It thus happened that many of these patients sought medical advice for sequelæ in whom the true significance of the original illness had escaped notice. In these cases diagnosis must be retrospective and depended largely on the history. He quoted the case of a young woman very severely affected by the Parkinsonian syndrome, whose original illness had been so slight that she neither went to bed with it nor sought medical advice. He had seen several other cases of this ambulatory type. In the presence of the Parkinsonian syndrome the retrospective diagnosis was, as a rule, easy. In other instances it might be more difficult. He cited the case of a man complaining of lassitude and presenting signs of minute involvement of the cranial nerves. On inquiry a history was obtained of a mild attack of encephalitis three months previously. Six months after the onset of this original illness he began to develop choreo-athetoid movements. These were controlled by hyoscine and had finally disappeared. The latent interval between the original illness and the development of the Parkinsonian syndrome might in his experience be as long as three years, but in these cases the patient could never fairly be said to have made a complete recovery from the original illness. If the patient recovered his mental and physical health after an attack and maintained this recovery for six months he thought he was free from further trouble. The involuntary movements received perhaps more than a fair share of attention. He had been especially interested in complaints of visceral sensory disturbance, such as sensations of suffocation, choking, nasal obstruction, and rectal tenesmus. Some of the sniffing and gasping movements seen in these patients might be due to this cause.

Dr. C. A. McBride (London) referred to Economo's work, showing that the virus might smoulder in the disease for a long period. He would confine most of his remarks to the occurrence of involuntary movements resembling those of spasmodic torticollis, and described two cases in detail to illustrate his remarks. We had learned from encephalitis lethargica that the symptoms of paralysis agitans might have an infective origin. Might this not be equally true of spasmodic torticollis?

Dr. Morris remarked that he had seen cases in which affections of the skin were distressing. He instanced hyperidrosis of the hands and trophic ulcer of the heel. He had also seen involuntary gaping movements of the jaw, which were accompanied by no sense of distress, but were beyond the patient's control.

Dr. W. A. Potts felt grateful to Dr. Buzzard for the explanation he had offered of the remarkable variations in the course of the disease, and quoted the case of a young woman who was completely stuporose one day and active on the next. As to treatment he thought that psychotherapy was certainly of value. In view of the calcification of the vessels recorded by Dr. McAlpine, had the administration of citric acid been tried? In some cases he had tried influenzal vaccines he had thought with some effect. He referred to two cases he had seen in a maternity hospital in which an erroneous diagnosis of eclampsia had been made, and in one case labour induced, in pregnant women suffering from encephalitis lethargica.

Dr. C. Charnock Smith (Hastings) referred to a case in which, on the advice of a colleague, he had injected turpentine into the leg—he was not sure whether this had been followed by beneficial results. He also mentioned the occurrence of confused mental states, especially in the evenings.

Dr. W. Hardcastle (Newcastle-on-Tyne) inquired as to the frequency of depression occurring as a sequel. When it did occur did it depend upon organic changes in the brain, or was it of psychogenic origin? He thought possibly that some of these cases might be helped with psycho-analysis.

Dr. Devine said, in relation to the statistics obtained from mental hospitals, that the psychiatrists had possibly overlooked a number of the cases in which the original illness had been of the mild or ambulatory type. He thought the correlation of the infective origin of this disease, and the nature of the mental symptoms observed, was of the greatest importance to psychiatry. Fundamentally we must conclude that all abnormalities of mental function depended upon changes of structure, however slight.

Dr. Macfie Campbell referred to the importance, from the point of view of treatment, of deciding whether symptoms were residual or whether they depended upon changes still active. Should one encourage the patient with Parkinsonian symptoms to rest or to make further efforts? He thought that further investigation of the cerebro-spinal fluid should be made in these late cases. With regard to the mental sequelæ, he had observed a marked difference between the reaction of the child and that of the adult. The former had frequently to be admitted to a mental institution on account of his anti-social outbursts. If the adult had to be placed under care, it was rather because his apathy rendered him unfit to look after himself. What was the explanation of this discrepancy in reaction?

Dr. **Buzzard**, in reply, said that as a result of the discussion we must conclude that an absolute distinction between relapses and true sequelæ was impossible. We must also remember that we knew little of the immunity conferred by an attack. Dr. Riddoch's case might have been, perhaps, an instance of two separate attacks occurring in the same person. When he referred to psychotherapy as an aid to treatment in the disease, he meant that one should ascertain what were the patient's own hopes and fears about his illness, and endeavour to allay needless anxieties. Having achieved this, one was in a much better position to carry out physio-therapy successfully. With regard to the pathological report of Dr. McAlpine, he thought that a calcified vessel, however wide its lumen, must be considered inadequate to provide a proper circulation.

Friday, July 27th.

At the closing session, Dr. G. **Riddoch** being in the chair, a discussion on the

Prognosis of Psychoses During Adolescence

was introduced by Dr. D. K. **Henderson** (Glasgow). In order, he said, to keep the discussion within limits, he would formulate his views as to prognosis, especially in regard to the type of mental reactions ordinarily called the dementia præcox type. Nothing was more tragic than the occurrence of mental disorder at the time of adolescence. Unfortunately disorders of conduct were often glossed over by the parents, and thus the opportunity for preventive treatment was lost.

The attitude which we adopted with regard to prognosis in general must be largely based upon the views we held concerning the mechanism of the disorder. We could either regard cases as developing upon the basis of some kind of organic visceral disease, or we could utilise the broader conception of psychobiological adjustment. Kraepelin's classification differentiating the manic-depressive and dementia præcox groups had been valuable as a stimulus to careful observation of symptoms, but in the opinion of the speaker symptoms alone were an unsafe basis for prognosis. The setting in which they occurred had also to be considered. Kraepelin's conception tended to breed pessimism in that it encouraged the idea that certain symptoms were characteristic of dementia præcox, and this carried with it a hopeless prognosis. In 1911 Bleuler had coined the term schizophrenia to include all cases except the manic-depressive group. This group of Bleuler's was a wide one, and according to his figures only 22 per cent. of the cases showed a severe degree of deterioration, but in the others there was always some residual defect. McCarthy had lately divided the cases of the dementia præcox types into two groups: (1) degenerative, and (2) non-degenerative; the latter, curable, group was subdivided according to the supposed toxic or infective factors in the ætiology. Cotton and his co-workers had been working on much the same principles, and had laid great stress upon the importance of focal infection, reporting a high percentage of recoveries as the result of treatment on these lines. He believed, however, that a wider conception was necessary. Although the possibilities of focal infection and of endocrine disturbances must be kept in mind, we must also estimate the psychic factors at their proper value, and consider the personality as a whole. The work of Freud and Jung had provided a great stimulus to research on these lines. He also wished to draw particular attention to the work of Meyer, who first emphasised the importance of considering mental illness in terms not of clean-cut groups but of reaction types. If we acted upon this conception we need not hesitate to diagnose a patient as belonging to the dementia præcox type of reaction; it did not follow necessarily that the prognosis was hopeless. He quoted in detail two cases illustrating the value of this method of approach to individual cases. One had to recognise in these cases both the constitutional defect and the good potentialities which might be developed and enable the individual to react to the illness in a satisfactory manner. Four other cases were related in which individuals showed symptoms, which might, in themselves, have been regarded as carrying a grave prognosis, but who nevertheless made good recoveries. When one considered these cases as individual problems in the light of the psychobiological conception, the recovery in each instance was intelligible. During the war he had reported a group of cases, which he termed the dementia præcox type of reaction occurring in soldiers, and pointed out that, as a rule, they reacted quickly to treatment and made good adjustments. This was due to the fact that the stress of war environment brought symptoms to the surface at an earlier period than would have occurred in civil life.

He attached great importance to occupational treatment in such cases. By this means outside interests might be so far developed that patients would learn to keep themselves in hand, and although they might not gain a complete insight into the actual nature of their illness, they might make a satisfactory social adjustment. There was no doubt, in his opinion, that if cases came under observation and treatment early the prognosis was very much better than it otherwise would be. The trend of public opinion was in that direction. More psychiatric clinics and out-patient departments were being established, and he believed that this would gradually lead to a more hopeful view in regard to the prognosis in these cases of so-called functional brain disorder.

Sir **Frederick Mott** (London) said that although he personally had devoted more attention to the neuropathological side of the subject under discussion, he was equally interested in its psychogenic aspect. Every case was a separate biological problem, and we should avoid attempts at rigid classification. The individual constitution should be carefully considered as well as the environmental stress. There were people whom one could knock on the head, fill up with alcohol, or give them syphilis, and they would never develop insanity. There were others who would readily break down under any one of these stresses. In this connexion he referred to the work of Gordon on similar and dissimilar twins, which demonstrated conclusively the importance of the constitutional factor. He had, however, for some time been interested in atrophic changes which he had observed in the genital glands in cases of dementia præcox. He quoted the case of a young man who died in hospital a month after a gunshot wound of the brain. He had originally taken the testes from this case as part of his control material. He was surprised, however, to find atrophic changes. Inquiry showed that the death had almost certainly been due to suicide. Some time later he had the opportunity to see a brother of this man in an asylum. After his death he found exactly similar changes in the testes. He subsequently discovered that there was a sister also in an asylum, that the father had died insane, and that there was insanity also in the mother's family. Here was an example of genetic inadequacy.

The war had illustrated the importance of the environmental factor, and had brought a number of cases of potential dementia præcox to the surface. Perhaps this might have been prevented by a more careful examination of recruits. He had found in these cases of dementia præcox, in the interstitial cells of the testes, in the adrenals, and the pituitary, disorderly arrangement and deficient staining of the nuclei. He next turned his attention to the nerve cells and in cases of dementia præcox found a deficiency of chromatin. As to the treatment of these cases by sheltering them from environmental stress—was this a good thing for the race? His studies of heredity in these cases had shown him that anticipation occurred in successive generations, and that in this way nature attempted to get rid of a defective stock.

Dr. F. E. STOKES (Portsmouth) presented statistics from the Borough Mental Hospital of Portsmouth relating to the recovery-rate in cases of adolescent insanity. These figures covered the post-war period. The male recovery-rate proved higher than the female by 10 per cent. As a fair proportion of the males were soldiers, this discrepancy appeared to be explicable in the light of the importance played by exogenous factors in precipating the disease.

Dr. DEVINE thought that psychiatrists owed a great debt to the inspiration of August Hoch. In each case it was necessary to study the individual reaction type, which was the soil upon which the psychosis grew. If we found that a psychosis had developed upon the basis of a shut-in personality as a practical matter we could be fairly sure that the prognosis was a bad one. He agreed with Dr. Henderson as to the important part played by war stress in the development of dementia præcox-like symptoms in the soldier. His experience with civilian cases had been similar. If the onset of the disease had been sudden and the precipating causes adequate the prognosis was good. He referred to the case of a young woman, whose history, so far as he could ascertain at the time, was that of a normal individual. The story of the onset was that in some amateur theatricals she had to take the part of a man. This brought to the surface a latent homosexual trend, which developed into the fantastic belief that she was a man. Here he felt that the prognosis was good, but in point of fact she became worse and had shown no signs of recovery. However, when he went deeper into the history he found that the girl had in reality been suffering from hallucinations for some years before the final collapse.

Another case to which he referred was that of an only son with a strong mother-fixation, who had failed to adapt to war stress. Judged by the symptoms, which were those of a confused dementia-præcox-like state, prognosis appeared bad. However, the patient eventually left hospital and became married to a woman much older than himself. This situation provided him with a partner who was prepared to fuss over him and demand little demonstrative affection in return, and at the same time the age of his wife was an effective barrier to the responsibilities which would have been entailed by a family. Under these circumstances he remained well.

Dr. SYMONDS, in discussing the fact that patients often fail to come within the range of proper treatment until the stage for preventive treatment is passed, agreed with Dr. Henderson that this was due largely to ignorance of the public, who either overlooked peculiarities of conduct, or took refuge in the blessed excuse of "nerves." The fault, however, was not wholly with the layman ; the average medical student in his curriculum had little or no chance of gaining any practical experience of mental disorders. He therefore often went into practice feeling that the psychiatrist alone was competent to deal with such cases—hence the regrettable tendency even in the medical profession to encourage the hypothesis of "nerves."

The remedy for this defect in the system of medical education lay in the provision of observation wards for mental cases in the general teaching hospitals. The very fact of the existence of such wards would make the student realise that the treatment of mental disease was an integral part of medical practice. The student would have the opportunity of learning to handle these cases and think about them from a common-sense standpoint. The hospital patient also would be encouraged to find help for the solution of his problems outside the walls of a mental institution. These patients did in fact attend the out-patient departments of general hospitals in large numbers, but in London at any rate facilities for their treatment as in-patients was sadly lacking.

In the future treatment of these cases he felt that closer coöperation was needed between the psychiatrist and the general practitioner. This, he thought, would come when the practitioner had an opportunity of practical experience in this work as a student, and when pyschiatrists in general learned to talk about their subject as intelligibly as Dr. Henderson had done. For hospital cases much more might be done in the way of after-care by means of a properly organised social service.

Dr. J. L. JACKSON (Fareham) hoped that Dr. Henderson in his reply would say something more about the treatment of these cases. As medical superintendent of a county asylum, he himself was in charge of 1100 patients, and with a limited staff felt keenly the difficulty in providing adequate treatment. Psychiatry had tended to become divorced from general medicine, and he welcomed every opportunity of bridging this gap. He was glad that Dr. Henderson had mentioned the possibility of a social recovery as opposed to mental recovery. There was no doubt that a good many patients were able to make a more or less satisfactory adjustment to the social environment even if they lacked insight. He regarded occupational therapy as one of the most important means of treatment. At the institution where he worked he had organised games and amusement committees with most satisfactory results.

Dr. D. STONE (Northampton) referred to the large number of cases which he encountered in general practice which never came within the ken of the specialist. Unfortunately, there was no specific remedy for mental disorders. Of what value was it to consult a text-book upon, say, psychasthenia ? The individual case had to be studied on its own merits. One had to find out what were the latent interests of the individual and develop them so far as possible in relation to his environment. He quoted the case of a young man who had failed to adapt himself to the requirements of business life, into which he had been launched by his parents. He had frequently expressed a desire to go to sea, which had been suppressed. Finally he was allowed to follow his own bent, went to sea on a whaler, and became an expert harpoonist of considerable renown.

Dr. H. BAIRD (Hastings) thought that it would be impracticable to undertake the treatment of mental patients in a general hospital. He considered the average duration of stay and the difficulty of caring for excited cases serious objections. The proper place for the mental patient was the local mental hospital. He thought that more use might be made of these hospitals for the purposes of teaching.

Dr. D. MATTHEW (Exeter) had been much interested in the effect of occupational therapy and exercise in preventing the development of catatonic conditions in dementia præcox cases. Other speakers had stressed the importance of the environmental factor in cases of mental disease. He thought much might be done also in some instances by means of psycho-analysis to change the patient's mental attitude.

Dr. RIDDOCH strongly supported the view that the establishment of mental observation wards in the general teaching hospitals was essential if the medical practitioner were to gain a clearer understanding of the problems of mental disease. Dr. Baird had said that provision was already made for the teaching of psychiatry at existing mental hospitals. Unfortunately the medical student, as a rule, was in the habit of regarding the demonstrations held in such hospitals rather as a spectacle in which he might take a detached interest than as an opportunity for gaining any real insight into the problems involved. If he were to learn anything of real value about these cases he must be given more responsibility and better opportunities of practical experience. As to the importance of the environmental factor, especially in the after-treatment of mental cases, how far might not the State be considered responsible for the after-care of mental patients, as well as their temporary shelter in asylums ? He thought that the after-care was equally important. He was especially interested in Dr. Henderson's remarks about the possibility of social recovery with lack of insight which he had so clearly illustrated in his cases.

Dr. HENDERSON, in his reply, said that he was encouraged to think that interest in these problems was growing. He thought the education of the student in psychiatry a matter of great importance. At Glasgow an out-patient clinic had lately been established where the student was taught to observe the social aspects of mental illness. The fault of the older psychiatric teaching had been that, although it presented the student with a vivid symptom-picture, it did not safely stress the importance of the history. In cases of mental disorder the history was just as important as in any other disease. Before considering prognosis or treatment one must know the facts.

With regard to treatment, he had been much impressed by his experience in the U.S.A. of the good results obtained by occupational therapy. This must be organised on a satisfactory basis if it were to be of any use. At the hospital where he worked he had recently succeeded in obtaining the services of an occupational instructor, and the scheme had already proved so successful that he had added to this important branch of his staff. He now had over 100 patients engaged every morning at one of four different kinds of handicraft. The result was that patients who had been in hospital for years and had sat about doing nothing were now getting satisfaction out of their work. The wards were easier to manage, and there was less demand for sedative drugs and for restraint. In allowing these patients to have in their possession tools such as might be used for weapons, one must be prepared to take reasonable risks.

He thought that mental hospitals should have the benefit of a consulting staff of medical and surgical specialists in order to preserve the perspective of the psychiatric staff and keep them in touch with the advances of general medicine. In connexion with the after-care of these patients, out-patient work had not yet been sufficiently developed. It should be possible for each one of these cases to have access in time of need to some physician upon whom he knew he could depend for sympathy and understanding.

Corrigendum.—In the report of Dr. E. P. Poulton's remarks on the relation of acidosis to rickets, at the Section of Diseases of Children (THE LANCET, August 18th, p. 361), the work carried out at Guy's Hospital was done by Drs. Osman and *Burgess*, and not as stated. We regret the error.

SUSSEX PROVIDENT SCHEME.—The question of the administration of the Sussex Provident Scheme has recently been discussed at length by the medical profession of the county. It was decided that as the scheme was supported by three parties—the subscribers, the doctors who gave their services free, and the lay representatives of the hospitals—the medical profession should be represented on the committee of the scheme and should elect their own representatives. The matter has arisen in consequence of the proposals put forward by the Royal Sussex County Hospital for the formation of a contributory arrangement to extend the facilities of the scheme by adopting a system of mass contributions of 2*d.* a week, instead of 3*d.*, from persons in receipt of less than 40*s.* a week. The majority of the hospitals consulted on the matter have accepted the proposals necessitating a change in the constitution of the executive committee to carry on the new régime. At a meeting of representatives of bodies coöperating with the scheme at Brighton on August 13th, it was decided that each hospital coöperating be asked to nominate two members for election to serve on the committee, one member, a medical man, to be nominated by the hon. medical staff of each hospital, and one member, a layman, to be nominated by the committee of management of the hospital, the subscribers to the provident scheme to elect from such nominees two medical men and two laymen. Although this was declared to have been carried unanimously, Dr. L. A. Parry, as representing 400 doctors in Sussex, said that while he could not possibly accept the resolution on behalf of the medical profession, he would do his best to get them to accept it as a compromise.

BIOMATHEMATICS.

Being the Principles of Mathematics for Students of Biological Science. By W. M. FELDMAN, M.D., B.S. Lond., F.R.S. Edin. With an Introduction by Sir WILLIAM M. BAYLISS, D.Sc, F.R.S. London: Charles Griffin and Co. 1923. Pp. 398. 21*s.*

AN experienced reviewer of medical literature into whose hands Dr. Feldman's book came inquired whether "all medical students nowadays have to know mathematics of that kind?" If by student we are to understand those technically *in statu pupillari*, the answer is a decided negative. It will be long enough before even the simplest differential equation finds a place in a paper set for an honours M.D. Hard as are the hearts of the Board of Examiners for the Primary F.R.C.S., the calculation of the effective component of the biceps will never reduce still further the attenuated ranks of those who satisfy the Board. But if by student we mean someone verily *studiosus*, a seeker of knowledge rather than diplomas, the negative is much less decided. In his introduction to Dr. Feldman's book, Sir William Bayliss indicates wide ranges of knowledge access to which is not easy to him who knows some algebra, but is impossible to any other. Turn where we will, to biochemistry, to epidemiology, to ophthalmic medicine and surgery, to general physiology, we are sooner or later confronted with the language of the mathematician; the student *must* learn the grammar of that language. But—and the distinction is a highly important one—this is not the same thing as saying that the medical student must be a mathematician. If that were essential, the outlook would be desperate, because mathematicians are certainly as rare as poets.

To one of these, Dr. Feldman's definition of mathematics as "the science and art of rapid and accurate computation"—Dr. Feldman admits it to be incomplete and might have used a stronger qualification—would be provocative of angry mirth. We shall be fortunate if once in a century one of these rare spirits, such a one as Hermann v. Helmholtz, devotes himself to the advancement of medical science. But although study of X.'s "French in three months without a master" will not turn a man into a serious rival of Anatole France, it will open to him a new world. Dr. Feldman has attempted to cut a track into a still more fascinating world, and, in our opinion, has attained a very creditable measure of success. He has several competitors, but none, except perhaps Salpeter—whose book besides being in German is too difficult for English medical students—has covered so wide a field. The amount of previous knowledge assumed is trivial, every method described is illustrated by a really interesting example and full use is made of diagrams. Anyone who has read the book carefully will not only be able to understand the language of more than nine-tenths of medico-mathematical papers, but will be in a position to continue his study of some particular branch of mathematics relevant to his own line of investigation. Dr. Feldman's sections on differentials and differential equations seem to us especially good, although the somewhat perplexing idea of partial and total differentials would have been made easier to follow with the help of a diagram, and the chapter on "Mathematical Analysis Applied to the Coördination of Experimental Results" is very helpful. The reader must of course never forget that although the successful representation of experimental results by a mathematical formula is a necessary condition of the latter's validity, it is not a sufficient condition. Observations may be, and often are, very effectively smoothed by a function which cannot possibly be regarded as the "law" of the phenomenon.

The chapter on "Biometrics" is not the best in the book; it is avowedly based upon a text-book written for students with a wider knowledge of algebra than readers of Dr. Feldman's manual will generally command, so that undue emphasis is given to methods and results of more interest to mathematicians than to experimental workers. But this defect is the less important because Yule's treatise on statistics is available to all. Dr. Feldman richly deserves the gratitude of the medical reader, and we hope that his book will be widely studied.

Inborn Errors of Metabolism.

Second edition. By Archibald E. Garrod, K.C.M.G., D.M., LL.D., F.R.S., F.R.C.P., Regius Professor of Medicine in the University of Oxford; Consulting Physician to St. Bartholomew's Hospital and to the Hospital for Sick Children. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 213. 7*s.* 6*d.*

Prof. Garrod's book is too well known to need introduction. Originally published in 1909 as the author's Croonian Lectures, delivered before the Royal College of Physicians in 1908, the volume was an immediate success, and it is quite safe to say that the second edition will have a similar popularity. The author confines himself to six "errors"—namely, albinism, alcaptonuria, cystinuria, hæmatoporphyria congenita, congenital steatorrhœa, and pentosuria. In the first chapter he deals with the chemistry of the species, pointing out that the metabolic processes are always the same for any given animal and that they always breed true except in cases showing an inborn error. He corrects the prevalent idea that if any abnormal substance is produced through a faulty metabolism, a new process is evolved to metabolise it. Study of the inborn errors of metabolism proves that this is not the case, since the abnormal substance is excreted unchanged. Alcaptonuria and cystinuria are examples of this. The second chapter is devoted to a statistical study of the rate of incidence of these rare diseases. The chapters dealing with hæmatoporphyria and steatorrhœa are entirely new; these two congenital diseases, although rare, are none the less interesting. The other chapters have been extended and brought up to date.

Throughout the book the author develops the idea that all the inborn errors have a common basis in their ætiology—namely, the lack of some ferment which is present in the normal body. Research in metabolism has shown that each step in the utilisation of substances such as proteins, fats, or carbohydrates is accomplished in stages, with an enzyme responsible for each chemical reaction involved. In some cases the enzyme is non-specific, acting equally well for, let us say, the oxidation of one oxy acid as another, but in the majority of reactions it becomes apparent that the ferments are specific to each. Prof. Gowland Hopkins's work on glutathione demonstrates very beautifully the importance of these tissue enzymes. All the inborn errors of metabolism can be explained on the assumption that some particular enzyme which normally destroys the abnormal substance in question is lacking in that particular patient. All workers appear to be agreed that cystinuria and alcaptonuria are due to the lack of the specific ferment responsible for the oxidation of these substances, but in the case of albinism there seems to be some difference in opinion. Thus Karl Pearson, Nettleship, and Usher suggest that melanin may not reach the pigment cells or that they have lost the power of storing the pigment. But, as Prof. Garrod points out, what is more likely than that this lack of the power of storing melanin is passed on by the gametes through the medium of the absence of a ferment. Moreover, the experimental work of Bloch and others demonstrates clearly that the absence of an enzyme is the best explanation of albinism. The inclusion of congenital steatorrhœa as one of the inborn errors of metabolism will occasion some surprise. Somehow or other one has not been in the habit of regarding this rare disease as belonging to this category, yet after reading the author's account of it one feels that it is quite just. Congenital steatorrhœa possesses all the essential attributes of an inborn error. The author allots the blame to the pancreas, attributing the disease to the lack of some unknown enzyme of the pancreatic juice which is essential to the digestion and absorption of fats. No substantial evidence of pancreatic disease in this condition has yet been obtained, but Prof. Garrod's explanation fits the facts very nicely.

The volume is written in a lucid manner and, unlike most treatises on metabolism, can be read and understood by most of us. Though the diseases described are so rare that they do not enter into practical medicine, the book will be read by the student of metabolism because of the light these pathological processes throw on normal metabolism, and by the medical man, because of the fascinating way in which the author deals with his subject.

The Debt of Medicine to the Fine Arts.

By J. A. Nixon, C.M.G., M.D. Cantab., F.R.C.P. Bristol: J. W. Arrowsmith. 1923. Pp. 29. 2*s.* 6*d.*

This little book is a reprint of the presidential address delivered last autumn at the opening of the fiftieth session of the Bristol Medico-Chirurgical Society. In it Dr. Nixon records in a pleasant fashion the many debts which medicine owes to the fine arts from the times of ancient Greece downwards. His argument is that the artistic sense is an aid to medicine, not only directly, as in the case of the beautiful anatomical studies of Leonardo and in Caspar's plates to Vesalius's anatomy, but also indirectly, as, for instance, that Hippocrates was inspired to draw his effective pictures of diseased conditions by the artistic sense of the age in which he lived. For a man to be able to put down upon paper an accurate picture of what he sees means that he can memorise or have a mental image of what he sees, and he quotes Paget, himself no mean draughtsman, who says of the power of drawing, "It helped to enable me to look and see more in things than some could see." We rather wonder that Dr. Nixon did not mention three medical men who made a reputation as artists, two of whom are dead—namely, Prescott Hewitt and Seymour Haden—and one alive, Henry Tonks.

Effects of Light on Life.

Grundzüge der Lichtbiologie und Lichtpathologie. By Prof. Walther Hausmann. (Eighth supplementary volume to "Strahlentherapie.") Berlin and Vienna: Urban and Schwarzenberg. 1923. Pp. 230. 15 pre-war marks.

Prof. Hausmann brings together, within the compass of a book of 230 pages, all that is known regarding the influence of light upon living organisms. Such a book gains much in value when, as in this case, the author is one of those who have contributed materially to our knowledge of the matters of which it treats. Prof. Hausmann's attitude is judicial throughout the work, and the many difficulties met with in the interpretation of the results of observation and experiment are by no means minimised. Sometimes, indeed, we may even feel that his caution is excessive.

Of the 12 chapters into which the book is divided, the first nine treat of the physiological aspects of the subject; the relations of photochemistry to photobiology; the general effects of light upon living organisms, and its more special influence upon the growth and movements of plants and animals. The action of light upon the superficial and deep tissues of man and the higher animals is discussed, and the part played by surface pigmentation in protecting the underlying structures. The chapters which deal with the production of disease by light are of special interest. In normal organisms these effects are very limited, but certain chemical substances, and especially fluorescent pigments, have the property of rendering the tissues highly photo-sensitive. Thus eosine administered for considerable periods for the treatment of epilepsy is capable, as Prime has shown, of rendering a patient subject to grave lesions of the skin and nails when he is exposed to bright sunlight; and domesticated animals which have been fed upon vegetable foods containing exogenous sensitising agents, such as buckwheat or Swedish clover, are liable to develop lesions of the skin and hoofs, and the diseases so induced are not infrequently fatal. Only unpigmented animals suffer severely, but piebald animals develop an affection of the skin of the unpigmented areas of skin.

The only disease known to result from the presence in the tissues of an endogenous photo-sensitising agent is hydroa vacciniforme, which is, in not a few cases, associated with porphyrinuria, and especially with congenital porphyrinuria. It was the author himself who showed that hæmatoporphyrin has a powerful photo-sensitising action upon lowly forms of life, and also upon white mice. After injection of hæmatoporphyrin the mice die quickly if exposed to bright light; in subdued light they develop a chronic light disease, whereas if kept in the dark they do not suffer any harm. Prof. Hausmann gives an excellent discussion of this subject, and of certain difficulties which it presents. Other human maladies in which light is apparently an exciting or modifying cause, but in which the photo-sensitising agent is unknown, are also discussed. A chapter is devoted to the fatal effects of light upon sensitive animal and vegetable organisms, and the concluding chapter of the book deals with the therapeutic action of light upon tuberculous lesions.

In compiling this book Prof. Hausmann has done a great service to physiologists and pathologists alike.

MICRO-BIOLOGY.

Handbuch der mikrobiologischen Technik. Band I., 2 Hälfte. 3 und 4 Abteilung.: Nährboden und Züchtung. By Prof. Dr. RUDOLF KRAUS, Direktor des Serotherapeutischen Institutes in Butantan-San Paolo (Brasilien), und Prof. Dr. PAUL UHLENHUTH, Geh. Rat., Direktor des Institutes für Experiment. Therapie Emil v. Behring in Marburg a.d. Lahn. Berlin u. Wien: Urban und Schwarzenberg. 1923. Pp. 535–817.

THE two sections which are here under consideration constitute the second part of the first volume of this book, which will be complete in two volumes. The present part has been written in seven chapters by different well-known authors: E. Gildermeister, W. Nöller, W. v. Drigalski, R. Doerr, E. Ungermann, E. Küster, M. Neisser, and K. Beckey, each of whom provides a separate part. The whole work is, no doubt, intended to provide an up-to-date treatise comparable to the second and third volumes of Kolle and Wassermann's handbook. The text, if not quite so comprehensive, is, on the whole, more readable, and appears to have been more critically compiled than in the latter exhaustive work. Sections 3 and 4 treat of the more generally applicable kinds of culture-media and the technique of aerobic methods. Anaerobic technique and some special methods of culture will, no doubt, find place in the second volume. Several of the procedures for renovating used culture-media, which came into use during the war for the sake of economy, are given in detail. The technique for the cultivation of protozoa is well dealt with in nearly 40 pages by Nöller. The complete work promises to be a most useful book of reference. A list of the authors quoted is given at the end of each article, including the full titles of the papers.

HANDBOOK OF PHYSIOLOGY.

Sixteenth edition. By W. D. HALLIBURTON, M.D., LL.D., F.R.C.P., F.R.S., Professor of Physiology, King's College, London. London: John Murray. 1923. Pp. 968. 21*s.*

THERE is certainly no living British physiologist to whom this book was not familiar (either under its present title or as Kirkes's Handbook) as an established text-book in his earlier student days, and Mascagni's anxious figure displaying his lymphatics (now Fig. 194), or Bourgery's contemplative fellow showing his cerebro-spinal axis (Fig. 160) draw forth a sigh as we recall the time when we first bent over them. Although for three-quarters of a century this, our first guide, and best of students' text-books, has appeared in edition after edition, each has been better than the last. The present editor has himself seen through the press 16 out of the 28 editions since the book appeared in 1848, and will, we hope, give us more, for the improvements in the present edition are such as to bring the book right up to date and ensure its continued popularity. One pleasing addition to a book which has given shelter to many a passing theory in the course of the wonderful development which physiology has undergone, is the inclusion of portraits of some great physiologists of the past, two of whom, Ludwig and Claude Bernard, were still living in the early days of Kirkes's Handbook.

Excellent balance is maintained in this book between histological, chemical, and experimental physiology, and in these days of specialisation the student can still obtain a proper perspective from the reading of it to counteract, if need be, the oral instruction which they receive. We believe that this book which already extends a respectable distance into the past of British physiology will continue its advance, abreast of the subject, well into the future.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The July number contains the following articles: The Fixation of the Kidney, by A. H. Southam. The investigation described in this thesis was undertaken with a view of throwing further light upon the causation of displacements of the kidney. The perirenal fascia was studied by means of sections of the trunk of six fœtuses and seven adult bodies. Plaster casts of the renal fossæ were taken in other cases. The nature of the perirenal tissue was determined by histological sections. A complete fascial sheath was convincingly demonstrated enclosing the kidney, suprarenal and perirenal fat, and attached to the diaphragm, vertebræ, and transverse fascia. The pararenal fat lies behind this fascia, and is probably the site of origin of a perinephric abscess. The perirenal fascia is the greatest factor in maintaining the position of the kidney, for all its other attachments can be divided without affecting the mobility of the organ to any material degree. The perirenal fat is not of great importance, but it serves chiefly as a protection from injury. Little fat is present in young children. The intra-abdominal pressure is the second most important factor in the maintenance of the kidney in position. Movable kidney is much more common in women; this is due to the widening of the pelvis, which causes an alteration in the shape of the renal fossa. In the male the renal fossa is pear-shaped and narrow at its lower end, but in the female it is cylindrical and widens below. Additional factors in women are lack of muscle tone and the effects of pregnancy. The article is illustrated by three plates, which show clearly the various points made by the author.—Endocarditis Lenta (Chronic Ulcerative Endocarditis): A Note on Thirty Cases seen in Civil Practice since the War, by Carey F. Coombs. The most striking features in this series of cases are the high sex-incidence in the male, the frequency with which the aortic valves alone are affected, and the fact that the men attacked were, with one exception, of fine physique, good previous health, and had all undergone hard and prolonged war service. The author considers that there is evidence that fatigue is the most constant causal factor, and it is possible that the production of lactic acid in the muscles may increase the rate of growth of organisms of low virulence. This is in accordance with Walker Hall's recent bacteriological investigations. A plate is included showing the lesions as they affect the aortic valve.—A Clinical Investigation into the Relationship of the Fat-Soluble "A" Vitamin to the Ætiology of Rickets, by Douglas Galbraith. Another blow is here dealt at the vitamin theory of rickets. The investigation is clinical, children and not animals being studied. Severe rickets was found to occur in Glasgow in children with normal amounts of fat in their dietary, and the percentage of rickets in summer and in winter was lower in those on a fat-poor than in those on a fat-rich diet. In the summer spontaneous healing was seen, even when the children were fed upon a fat-poor diet. In the winter violet rays and massage proved the most successful therapeutic agents. The X-ray appearances of the bones in varying stages are well seen in the plates accompanying the article.—On the Phosphorus and Calcium of the Blood in Renal Disease, by O. L. V. de Wesselow. The inorganic constituents of the blood in renal disease were estimated, with a view to correlating changes in their amounts with variations in clinical symptoms. Seventy-four patients were investigated, including cases of nephritis, albuminuria of pregnancy, and a few of surgical affections of the urinary tract and cardio-vascular disease. The conclusions arrived at are that in cases of nephritis in which the prognosis is grave there is a marked retention of phosphates, and on the whole phosphate and urea excretion run parallel. The calcium content of the serum varies inversely with the phosphates, and a low calcium blood figure seems to be associated with the local muscular twitching in the late stages of uræmia.—A Comparative Study of Basal Metabolism in Normal Men, by Frederick Greig Hobson. There are many fundamental factors which influence the basal metabolic-rate, and the author has endeavoured to determine their relative importance in order to establish a normal base line for metabolism. The factor which varies most in the different methods for estimating basal metabolism is body size, as this has been calculated according to different formulæ. The author, as the result of observations on a large number of healthy individuals, considers that Dreyer's formula, using the calculated body weight instead of the observed body weight, gives very satisfactory results. The Benedict clinical calorimeter was used throughout, and certain defects are noted, and the methods adopted for their correction are described.—Critical Review. Jaundice: A Review of Recent Work, by J. W. McNee. This article opens with a reference to the important advances which have been made during the last ten years in America, France, Germany, and Holland, and which have revolutionised our views on the pathology of jaundice. A diagrammatic representation of a liver lobule is given as a basis for the new theory of jaundice which is detailed. The importance of Aschoff's "reticulo-endothelial system" is outlined, and the advances made possible by the van den Bergh test are described. For clinical instruction jaundice is classified as follows: (1) Obstructive hepatic, (2) toxic and infective hepatic, and (3) hæmolytic. In addition to an account of the technique employed in the van den Bergh test the article closes with a note on the "dissociated jaundice" of the French observers, in which it is claimed that in certain cases of hepatic disorders bilirubin alone may be retained in or reabsorbed into the blood, while the bile salts are excreted normally, or the reverse process may occur.

British Journal of Ophthalmology. July and August, 1923.—In the July issue J. B. Lawford and Humphrey Neame write on Binocular Choroidal Tuberculosis with Detachment of the Retina in two kittens, recording a probably unique observation. The kittens were of the same litter. In one case the presence of the tubercle bacillus was demonstrated in the affected choroid of one eye. In the other it was demonstrated not only in the eye but in various other organs and inoculation of a guinea-pig gave a positive result.—R. R. James has unearthed various cases of ophthalmological interest from the post-mortem records of St. George's Hospital.—A paper by the late Charles Killick tabulates 100 cases of cataract removed under a conjunctival bridge.——The August issue contains, besides an appreciation of the late George Critchett (1817–1882) in the "British Masters of Ophthalmology" series, by A. Maitland Ramsay, a paper by Miss Ida C. Mann on the Embryology of Congenital Crescents. These may occur in any part of the disc margin, but two-thirds of them are found below the disc and only a small proportion on the outer side, a fact which differentiates them from the acquired crescents of myopia. In the common form of congenital crescent the retinal pigment epithelium and also the nuclear layers have failed to reach the lower end of the nerve, so that a small area devoid of every layer except nerve-fibres is interpolated between the lower edge of the disc and the true lower edge of the nerve. The embryological cause of this is a slightly abnormal development of the choroidal fissure. This is explained by reference to the embryology of birds.—Also a communication (received through the Ministry of Health) from Gordon Norrie, who is doctor to the Copenhagen Royal Blind Institute, in which practically all blind children in Denmark are educated. Since 1900 it has been compulsory for every midwife to instil a solution of nitrate of silver, 1 : 150, into the eyes of the infant after birth. The result has been that blindness from ophthalmia neonatorum is almost eliminated in Denmark.

American Journal of Ophthalmology. May and June, 1923.—In the May issue: Iridotasis Operation for Glaucoma, by M. Goldenburg. This is the description of an operation similar to that of Colonel Herbert for effecting drainage by the inclusion of the iris in the scar. The author has practised the operation for five years with success.—N. Yoshida, of Japan, reports a case of acute glaucoma following Heine's cyclodialysis, an operation devised, but hardly practised in this country, for the cure of chronic glaucoma.—J. M. Thorington, by means of a single letter, a V, and a movable screen, claims to have devised a test for visual acuity superior to the ordinary test cards.—A. E. Foster reviews the literature of corneal grafting and adds some original experiments on cats, from which he concludes that a flap of the entire thickness of the cornea can be removed and replaced with an entirely satisfactory result, but that a transplantation from another species is a biologic impossibility.—In a statistical study of ophthalmia neonatorum in Philadelphia, L. Lehrfeld states that one instillation of any prophylactic is not a positive protection against the disease, and that a large proportion of the new-born do not receive any prophylactic at all. Blindness from this cause has not been materially reduced by the present methods of prevention, he says, and he advocates more stringent measures, including the use of argyrol in 25 per cent. solution on three successive days.——In the June issue H. D. Lamb reports two cases of ruptured choroid, illustrated by a plate. One of them is of unusual extent and shape.—C. E. Farree and G. Rand contribute a paper showing the influence of illumination on the size and form of the colour fields. The charts show how little dependence can be placed on breadth or shape of field and order of ranking as to breadth, either in diagnosis or in checking up the advance or recession of a pathologic condition, unless greater precautions are taken for the control of the intensity of the stimulus light than are possible in the conditions which ordinarily prevail in office and clinic work.—Two articles give instances of focal infection from teeth and tonsils. The first, by Clarence P. Jones, relates a very unusual case of interstitial keratitis, apparently of the typical syphilitic variety, but in which syphilis was excluded. It began to clear up at once on the removal of nine teeth with apical abscesses and also infected tonsils. The second article, by John Dunn, gives further instances of various ocular conditions due to focal infection. In two of them the removal of an old blind eye proved an effective remedy.—Of the remaining articles the most important is one by W. H. Nardin and R. S. Cunningham on familial retino-cerebral degeneration, which was annotated in our issue of August 18th.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 1, 1923.

POST-HOLIDAY LASSITUDE.

THAT it is not unusual for the worker of the modern city type to return from a long-expected holiday feeling rather more tired and worn-out than when he started is a matter of sufficiently common experience to have rendered it almost a truism that it requires a week to recover from a holiday. The point was well illustrated some time ago by Mr. HASELDEN in one of his trenchant cartoons, where he depicted the holiday-maker back from a period of unaccustomed swimming, tennis, and long tramps, wondering why he failed to feel recuperated. The cartoon served as an apt illustration of one aspect of the puzzling problem, what constitutes "form" and its absence. Apart from the body of purely empirical knowledge accumulated by generation upon generation of trainers both of men and of animals, there has, up to the present, been a very meagre understanding of the factors which go to make up this condition of "form." It is common knowledge that an amount of exercise which, indulged in immediately after a long period of sedentary existence, will produce nothing but exhaustion with its deleterious results, may be accomplished readily and easily, leaving its performer fitter than before, if led up to by a period of gradually increasing daily exercise. The application of this knowledge constitutes "training."

The factors underlying the acquisition of form—improvement in coördination, hypertrophy of muscles, speeding-up of the mechanism for the removal of metabolites—are not altogether unknown. Little attention has, however, been paid to the why and wherefore of the deleterious effects of heavy and unaccustomed exercise in untrained individuals. Some light is thrown upon this subject by observations recently made by an American worker, Dr. G. O. BROUN.[1] Using dogs as his subjects, this observer has obtained evidence to the effect that several days of hard muscular effort, following upon months of sedentary life, result in a pronounced destruction of the red cells of the blood; similar effort indulged in by animals which had been leading an open-air life with plenty of exercise, on the other hand, had no such effect. The dogs used in the experiments had been kept caged for several months, the cage in this instance serving as an excellent representation of the office of the city worker. They had been fed upon a "generous mixed diet containing considerable meat," in which again the parallelism with the conditions of the city worker is very evident. They were then exercised for several successive days upon a treadmill, the exercise being conducted for four hours daily, in spells of two hours with an interval of one hour. During one day's exercise they averaged a journey of about four miles at an inclination of 20°, or the equivalent to an ascent of something over a mile. It is recorded that in the early days of the experiment the dogs appeared very tired, but that by the end they showed all the signs of thorough enjoyment. Examinations of the blood as to the total volume of corpuscles by the hæmatocrit method and of the plasma by the vital-red procedure were made at frequent intervals before, during, and after the period of exercise. The findings showed a remarkable conformity; in every instance there was a marked decrease in the total corpuscular volume with a less marked increase in the plasma volume. After an average of a week's exercise, Dr. BROUN found that it took from one to three weeks for the corpuscular volume to return to its previous level. Interest centres on the reduction of the corpuscular volume, which in one case was as great as from 101 to 62 per cent. of the normal average. The author can find no explanation of his observed facts other than a considerable destruction of red cells. How this destruction is brought about is not evident, but it is suggested by Dr. BROUN that it is due to the mechanical injury of the red cells by the violently contracting muscles. One of the factors of training would appear to be the education of the hæmatopoietic system to replace the destroyed elements; in the untrained animal the response of new blood formation appears to be delayed, in this respect resembling the behaviour after hæmorrhage in a normal animal.

Hints of some such phenomenon of blood destruction accompanying unaccustomed exercise have been conveyed by previous observations; for instance, FEIGL[2] was able to demonstrate traces of hæmoglobin and hæmatin in the serum and urine of untrained soldiers after hard marching; but the present observations are up to now the clearest and most convincing on the subject. There has always been a tendency to look upon post-holiday lassitude as a purely psychic affair. It is worthy of note that the lassitude may have a physiological basis.

◆

DIVERTICULUM OF THE BLADDER.

DIVERTICULA of the urinary bladder, as distinct from the multiple sacculations seen in cases of urethral obstruction, are comparatively rarely met with. For this reason little general attention has been paid to them. This is the more unfortunate in that proper treatment is able to effect a complete cure of the symptoms which arise from them, whilst neglect is invariably followed by urinary troubles which are bound to lead eventually to the death of the patient, though the end may be delayed by years of ill-health and intermittent suffering. Mr. J. SWIFT JOLY, elsewhere in this issue, relates his experience of this condition. He has treated 14 cases by various methods, and has been able to trace the subsequent history of the majority of them. A perusal of his paper shows how many years it takes a urinary surgeon to acquire what, in comparison with many other diseases, must be considered a very moderate experience. The full description of his cases, therefore, together with the conclusions at which he has arrived, form a very valuable contribution to the subject, and will doubtless serve as a guide to other surgeons who have only had the opportunity of dealing with an occasional case. In a recent review[3] of this disease, Mr. W. GIRLING BALL relates the successful cure of two men by excision of the diverticulum, and gives a good account of views which have been held of the pathology of offsets from the bladder cavity.

The balance of evidence seems to be in favour of a congenital origin for these diverticula, very probably an abnormal budding out of the embryonic ureter. Curiously enough, they do not as a rule give rise to trouble until after the age 40, and the symptoms which call attention to them are then usually those of infection. The seriousness of the situation lies in the inability of the diverticulum to evacuate its contents. Once implanted there the infection proceeds almost unchecked in the stagnant contents. Not only has the wall of the recess but little muscular tissue in it so that collapse can only be brought about by increased general abdominal pressure, but when the bladder contracts it tends to close the communicating aperture, so shutting off the diverticular contents during micturition. This explains why, after the passage of a quantity of relatively clear urine, a patient, within a few minutes, may pass a volume of most offensive water. The diagnosis suspected from such symptoms as this is confirmed by cystoscopy or cystography. Of these the latter is the more certain, for whilst during the routine cystoscopy of a number of urinary cases diverticula will be seen from time to time, this form of examination may be very unsatisfactory in advanced cases of the disease. The true bladder cavity may be so contracted that there is no room for proper manipulation of the cystoscope; it may be almost impossible with the utmost patience to obtain a clear viewing medium, or the cystoscope may pass straight into the diverticulum so that a most perplexing picture is presented to the cystoscopist's astonished gaze. Cystography, on the other hand, will almost always reveal the presence of a diverticulum, though lateral or oblique views may be necessary.

---

[1] Blood Destruction After Exercise. Studies from the Rockefeller Institute for Medical Research. Reprints, vol. xlv., i. and ii., 7 and 27.

[2] Biochem. Zeitschr., 1916, lxxvi., 88.

[3] St. Bartholomew's Hospital Reports, vol. lvi., part 2.

In the treatment of vesical diverticula nothing short of radical removal of the sac is effective. Mr. Joly warns against preliminary suprapubic cystotomy with a view to combating infection. It makes matters rather worse, owing to the occlusion of the communicating aperture by the contracted bladder referred to above. If the renal function is so much damaged that any considerable operation is contraindicated, not only must the bladder be drained, but two small tubes should be introduced into the diverticulum for irrigation purposes. Extravesical preliminary drainage of the septic sac renders subsequent removal, in the best of circumstances, a difficult operation, a still more troublesome procedure. Mr. Joly has tried all the recognised methods of excision, except that by which the diverticulum is reached by the sacral route. He favours, where possible, extra-peritoneal suprapubic excision. His advice when the serious problem of a coexisting prostatic obstruction confronts the surgeon is to remove, if possible, the prostate at the same time as the diverticulum. If the condition of the patient will not allow of this, the diverticulum should be removed first, and the prostate after a lapse of one or two weeks. The results of operation upon these cases depend upon the degree of infection already present, or, more accurately, whether a serious extension to the kidneys has taken place. When these organs are but little affected the results are excellent. The recognition of this fact raises the question of the advisability of removal of a diverticulum which may be discovered accidentally during a cystoscopy for some other urinary lesion. Such a measure may reasonably be held to be justifiable in view of the very serious consequences which ensue when infection takes place.

◆

OPERATIONS ON THE CARDIAC NERVES IN ANGINA PECTORIS.

Apart from the nerve ganglia which lie in the heart itself, there are two sets of nerves supplying the heart—namely, the sympathetic from the cervical ganglia and branches from the vagus. Recently attempts have been made to influence the pain in angina pectoris by operations on both these sets. Prof. Fritz Brünig,[1] of Berlin, reports the work hitherto undertaken in this direction. Experimental physiology teaches us that the accelerator fibres to the heart pass in the sympathetic, whereas the depressor fibres run in the vagus, but, as Dr. Brünig points out, these facts have been deduced from observations on animals, and recent advances in our knowledge have shown that there are often great differences between the vegetative functions in man and in animals, and therefore any such analogies must be accepted with caution. The fact that many heart conditions, especially angina pectoris, cause such great pain leads us to the conclusion that the nerves to the heart contain not only efferent but also afferent fibres, which bring the pain into consciousness. In 1899 Frank had the idea of resecting the cervical sympathetic and its ganglia to combat the pain in angina pectoris, and in 1916 Jonescu carried out the operation in one case. In 1922 he and Tuffier both reported a further successful case. In January, 1923, Dr. Brünig extirpated the left cervical sympathetic with good results, while in the beginning of this year Pleth and Coffey reported four or five similar operations, with one death. The operation consists in resecting the whole of the cervical sympathetic nerve with its ganglia, including the stellate ganglion, in this respect differing from the earlier operations for Graves's disease, epilepsy, and glaucoma, which left the last-named ganglion intact. In Dr. Brünig's case he succeeded not only in permanently relieving the pain, but also in checking the attacks of rise in blood pressure (at times over 100 mm. Hg) usually associated with the disease. This is significant, as repeated attacks of constriction of the blood-vessels (the cause of the rise in blood pressure) must in the end lead to changes in the walls of the vessels, and predispose to cerebral hæmorrhage. The results of the operation are, as shown by Jonescu's case (observed over eight years), permanent. Among the 12 cases reported there has only been one death, that of a man suffering from aortic syphilis and commencing aneurysm of the aorta. Dr. Brünig has now successfully operated on a further eight cases, some for other conditions.

That the results of the operation are satisfactory is not surprising, for we know that stimulation of the sympathetic causes contraction of unstriped muscle, as well in the intestinal canal as in the blood-vessels. We know also that stimulation of the vagus has an antagonising action, but it is extremely surprising when we hear from Eppinger and Hofer that they have achieved the same result in the same condition by division of the vagal cardiac branches. The reasoning that led them to try the operation was the conception that the pain in angina pectoris was caused by a vaso-motor contraction of the coronary arteries, which produced a dragging or irritation of the nerves surrounding the aorta, and that this stimulus was carried to the central nervous system by the cardiac branches of the vagus. Therefore, if these nerves were divided the pain would be relieved. Up to April of this year the operation has been carried out in six cases, three times unilateral and three times bilateral. All the cases were suffering from an aortalgia, as far as one can tell from the short accounts so far published, and there was no case of true vaso-motor angina pectoris among them. In five cases the attacks of pain were cured, while one died from paralysis of the vocal cords following injury to the recurrent laryngeal nerve. How is the fact to be explained that the interruption of two nerves hitherto believed to be antagonistic has the same effect in relieving the pain in angina pectoris? The suggestion that during the sympathetic operation the vagal cardiac branches are also injured is to Dr. Brünig, with his technique, inconceivable; but he thinks it is possible that the vagal branches are in reality sympathetic fibres arising in the superior cervical ganglion, passing through the dense plexus between the latter and the ganglion nodosum of the vagus, and out through the cardiac branches to the heart. Division, therefore, of the latter twigs would have the same result as extirpation of the sympathetic ganglion from which they arise.

---

[1] Deutsche Medizinische Wochenschrift, July 20th, 1923.

So far it has only been proved that division of the vagal branches is useful in cases of aortalgia; no cases of true angina pectoris have been so treated, nor do we know whether the attacks of rise of blood pressure would be influenced. On the contrary, if the so-called depressor nerve has identically the same function in man as it is known to have in animals—namely, to cause, on stimulation, a fall of blood pressure—it might be very risky to divide it on both sides, thereby cutting off a valuable safety-valve for the heart. The indication, therefore, for the vagus operation is very limited as compared with the sympathetic, for, first, it is only applicable to aortalgia, and, secondly, in cases of angina pectoris it may not be entirely without risk. But if it can be proved after extensive use that it still has good results, then it may be preferable, as being more conservative, and necessitating only division of a nerve as compared with resection of the whole cervical sympathetic chain. The technique of the vagus operation could, however, be simplified. Hofer traces the vagus nerve close up to the jugular foramen and then traces its branches down to the thorax, and only those which pass freely into the thorax are divided, but great difficulty must be experienced in avoiding the superior and inferior laryngeal nerves. Dr. Brünig therefore suggests that the carotid sheath should be opened for a distance of about 5 cm. in its lower portion, and that the whole sheath should be removed for a similar distance, leaving the vessels and vagus nerve bare in this region. By this means all the nerves running in the sheath must be divided, including the depressor. But he maintains that the sympathetic operation is the better, both physiologically and because it has a larger field of application. The future will, however, show which is preferable. One thing is certain, that operations on the cardiac nerves will increase our knowledge of their physiology, and therapy will thereby benefit.

THE FOURTH YEAR OF THE HEALTH MINISTRY.

The issue of the fourth annual report of the Ministry of Health, for the year ending on March 31st, 1923, coincides with the resignation of its head, on his translation from the charge of the nation's health to that of its finances. Whatever regret may be felt at the loss of Mr. Neville Chamberlain almost before he had time to make the wisdom and breadth of his outlook felt in public health matters, there are compensations in the destination to which he has been called. The history of the Ministry since its foundation, and of the efforts of Mr. Chamberlain's predecessors to cope with its problems, no less than the substance of this last report, show clearly that the work of the Ministry has been hampered throughout by lack of funds at its disposal. The new Chancellor of the Exchequer will at least have an intimate knowledge, for example, of the dire need of houses and of the steps being taken to promote and encourage building with the least possible cost to the nation. Some success has already been achieved in this direction. It is stated in the report that the amount which Parliament will be asked to vote as a grant in aid of the deficit on housing schemes is £8,710,000, nearly £1,000,000 less than in the preceding year. The provision of employment and relief of distress again have been attempted in two ways—indirectly through authorising loans to local authorities for expenditure on public works, and directly through grants for maternity and child welfare and for milk distribution. In this regard it is noted as gratifying that though the continued need for economy renders it impossible to contemplate extensions of this work on a large scale, local authorities are not only maintaining their existing services, but in many cases by more efficient administration are able to effect improvements. The position of tuberculosis schemes is not dissimilar; rigid examination of expenditure has enabled local authorities to provide at least the same amount of treatment as in the previous year, though the grants approved did not allow of important extensions. The situation is reminiscent of that of the little old woman of small means who housed her abundant progeny in a shoe and supplemented their inadequate diet with a liberal castigation. There must be a limit to the extent to which such stern methods can succeed, and we trust that the new Chancellor may see the need of allocating larger grants for health purposes. Meanwhile we welcome the new Minister of Health, Sir William Joynson-Hicks, who may expect to get at least a sympathetic hearing from his colleague at the Treasury.

In bidding farewell to Mr. Chamberlain we would call attention to the succinct memorandum which has just been issued by a departmental committee appointed by him on the subject of cancer. The personnel of the committee and the terms of the memorandum will be found on p. 479 of our present issue. Its object is to summarise in non-technical terms our present knowledge with regard to the ætiology and incidence of cancer, and to offer for the consideration of local health authorities some suggestions which may be useful to them in their efforts to inform public opinion on this important subject. Of the many leaflets attempting to summarise the cancer problem which have been submitted to us this one appears the most convincing and authoritative, and it will form a classical document of the state of knowledge in 1923. Apart from the appointment of this committee, we are informed that the Minister has directed the medical intelligence service of his Department to keep in touch with developments of cancer investigation, and that researches of an epidemiological and statistical character, both at home and internationally, in regard to cancer are in progress. Full and careful consideration will, moreover, be given to any means by which it would appear that the Ministry can use the resources at its disposal to aid cancer inquiries, in coöperation with the Medical Research Council or the special cancer laboratories and research institutions. This pronouncement does no more than confirm our confidence that responsible authorities at the Ministry of Health are fully alive to the anxiety felt by the public for the keen prosecution of cancer research. In this and in the many other medical and hygienic problems which will shortly engage him we trust that the period of office of the new Minister will be a fruitful one.

JOINT ACTION AGAINST VENEREAL DISEASES.

The National Council for Combating Venereal Diseases and the Society for the Prevention of Venereal Diseases, after each considering and unanimously accepting the Trevethin report, have decided to confer in order to determine what joint action can be taken for giving effect to the recommendations contained in the report. This conference will meet after the summer vacation. We welcome the prospect of these two societies working together for the common good, for it is the obvious duty of the medical profession to give guidance and assistance to the public in matters where medical experience counts for so much. The proposal to set up a medical tribunal, whose conclusions and recommendations could be submitted to public opinion, took shape as the result of correspondence 18 months ago between the then Minister of Health and the chairman of the Medical Consultative Committee. It must be cheering to Lord Dawson to see the fruition of his tireless effort. With united leadership a number of urgent questions regarding venereal disease still outstanding may achieve solution without delay.

Annotations.

"Ne quid nimis."

BRITISH ASSOCIATION AT LIVERPOOL.

The ninety-first annual meeting of the British Association for the Advancement of Science opens at Liverpool on Wednesday, Sept. 12th, when Sir Ernest Rutherford will deliver the presidential address on the Electrical Structure of Matter. On the following day Prof. G. H. Nuttall, who presides over the section of Physiology, will give an address on Symbiosis in Animals and Plants. Papers to be discussed at this section include one by Prof. J. J. R. Macleod on Insulin and its Value in Medicine, and one by Dr. F. W. Edridge-Green on the Effect of Blood in the Retina on Colour Equation. On Friday Prof. G. Elliot Smith will address a general meeting of the Association on the Study of Man. Local arrangements include excursions to places of interest and visits to works and factories. The Liverpool housing scheme will be inspected by one party and the waterworks of the town by another. Planter's margarine works, the lactose factory at Haslingden, and the Union Cold Storage Company's plant are among the industrial concerns to receive a visit. Public interest in the administration of mental hospitals is recognised in that an excursion is arranged to the County Mental Hospital at Rainhill. It is proposed, as usual, to give a series of public lectures during the meeting of the Association, in Liverpool and in surrounding towns, while four lectures will be arranged specially for young people. A scientific soirée will be held on Sunday evening, Sept. 16th. The sections will meet in the buildings of the University of Liverpool, while the reception room is in the large and centrally-situated St. George's Hall.

DUST INHALATION AND PULMONARY DISEASE.

Considerable attention has in recent years been paid to the effect of atmospheric pollution in causing lung diseases; hence special interest attaches to an unusually complete investigation recently carried out by Dr. E. L. Middleton, one of the medical inspectors of factories. The results are reported in two documents, and the reader is, for some reason unexplained, compelled to peruse both to understand the work in its entirety; this method of presentation will, we hope, not be made a precedent. The main report[1] is one of the best dealing with occupational risk issued from the Home Office. The processes concerned are well explained and clearly illustrated, so that those unfamiliar with industrial conditions can easily understand. These conditions vary immensely; in Sheffield tenement grinding "hulls" or "wheels" still exist, hopeless places of which it has been said they were *built*, not *designed*. Their low, discoloured ceilings, with swarf from the wet grinding accumulated on floor, walls, beams, working clothes, and the men themselves; dark, even on bright sunny days; damp, always; with an entire lack of all hygienic needs for cleanliness or welfare, all call urgently for rapid elimination from modern industrial life. Fortunately different workplaces exist in such up-to-date factories as those at Falkirk, Accrington, Wolverhampton, and Birmingham. Mechanical factors concerned with danger from the sudden fracture of rapidly revolving wheels, the structure of grindstones, and methods of removing or abating the dust danger, are fully dealt with, but medical readers will rather be interested in morbidity and mortality which prevail among the men, of whom 1153 were submitted to careful medical examination.

The findings are important, even though the conditions of the inquiry forbade recourse to X ray examination or prolonged observation. They establish that diminution of chest expansion due to age is not so important as that due to dust inhalation, and that the greatest loss of expansion occurs among those most exposed to the inhalation of fine silica dust. The resulting morbidity is discussed under the headings of tuberculosis, bronchial catarrh, bronchitis and pulmonary catarrh. Definite evidence of tuberculosis was found in 7·07 per cent. of wet sandstone hand-grinders (with their special exposure to silica dust), as compared with 2·76 for all other groups of men examined. Pulmonary tuberculosis associated with dust exposure was found to claim an undue proportion of its victims late in life; thus, whereas the apex of the curve for male deaths in Sheffield (not specially exposed to dust) was at age 40, that for Sheffield grinders and cutlers was about age 50. Those so affected possessed signs more or less pronounced of fibrosis of the silicotic type. Bronchial catarrh confined to the larger bronchi, on the other hand, was slightly more prevalent among glazers and dressers with considerable exposure to irritating dust having a low content of silica; indeed, the silica-stone workers were those least affected. Chronic bronchitis was found following upon established bronchial catarrh and associated in glazers and dressers with rather a different type of fibrosis from that caused by silica dust: a type which originates round the larger air-passages, in distinction to silicotic fibrosis, which originates in the alveolar areas. Pulmonary catarrh, distinguished by cough and "tightness on the chest," is described as depending on the presence of fibrosis and as being a sequela to it. It is peculiar to silicosis, and appears to have a bad prognosis.

This investigation, while it confirms the observations of others in reference to the toxic character of silica dust, is remarkable for establishing a train of clinical symptoms associated with inhalation of other dusts than silica, such as those composed of emery and other oxides of aluminium, and of carbide of silicon. Fibrosis, bronchitis, and pulmonary catarrh represent silicosis, which predisposes to tuberculosis, on the one hand, or may progress without that complication to a fatal issue. Bronchial catarrh and bronchitis with interstitial fibrosis, with no peculiar predisposition to tuberculosis, constitute a separate type of pneumonoconiosis which follows upon inhalation of irritating, but non-toxic, dusts. Fortunately for the health of the metal trade, grindstones are giving way to manufactured wheels which generate far less dust and are not composed of silica. Although more expensive to instal, they outlast the grindstones, are economical in the end, and do the work better. This change in the wheels used will probably do more in the next few years to eradicate tuberculous silicosis from the industry than any other possible preventive measure. Hence we note with gratification that the code of regulations proposed to control the industry bears far more heavily upon the users of grindstone wheels than of manufactured wheels; and also that a suggestion, which may accelerate the change, is made for granting compensation under the Workmen's Compensation (Silicosis) Act, 1918.

A careful and intensive inquiry into the amount and types of dust to which different processes give rise rounds off the investigation. The table in which the results—obtained by using Owens's dust-counter—are set forth is given as an appendix to the report, while the discussion of the results appears in the annual report.[2] Attention was paid in particular to the presence of fine particles of silica, which, on account of the physical and chemical form in which it occurs, is the prime cause of fibroid phthisis in the industries under review. The degree of danger was found to depend on the concentration of such dust in unit volume of air, but the visual appearance of the air was no criterion of the dust present. The most injurious dust is so fine that it floats in the air and is diffused far from its point of origin to become a source of danger to neighbouring workers. Evidence is adduced in favour of intermittent exposure, even though the second process followed has its own different dust risk. The efficiency of methods of dust prevention by the application of water at the grinding point, or of dust removal by localised exhaust draught, or of dust dilution by general ventilation, was estimated by dust-counts. The whole work provides a sound basis for administrative action and has added to scientific knowledge.

BRITISH JOURNAL OF ANÆSTHESIA.

WE welcome the first appearance of the *British Journal of Anæsthesia*, a publication that it is proposed to produce quarterly,[1] the contents of which are to be concerned entirely with anæsthetics and the practice of this special branch of medicine. The Editorial Board, the names of which appear on the cover, comprises representative anæsthetists from the great towns of England and Scotland. It is, however, the ambition of the promoters of the journal to make its scope Empire wide, and they hope to bring into association with themselves representatives of the British Dominions beyond the seas. The first number augurs well for the future success of the journal. It starts appropriately with an historical article from Sir D'Arcy Power, and this is followed by a long account of some clinical experimental work on the use of drugs in combination by E. P. Donovan and J. T. Gwathmey. W. J. McCardie writes on broncho-pulmonary complications following anæsthesia, J. Blomfield gives a digest of his experience of sacral analgesia, and there is an account of new anæsthetics by C. Langton Hewer and a comprehensive abstract and bibliography of current anæsthetic literature. It will be realised that the magazine is a most useful one for any practitioner much concerned with anæsthetics, and we have no doubt that if the journal goes on as it has begun it will be a valuable addition to periodic medical literature.

FREE INSULIN.

A MESSAGE from Toronto announces the free distribution of insulin to diabetics in the province of Ontario who present a certificate from their medical man that they are unable to meet the cost of the treatment. As a matter of cold argument there is doubtless much to be said on both sides of the question whether this is a sound social procedure. Doles of all kinds are objectionable. Those who have are already taxed sufficiently for the benefit of those who have not. Diabetes is not a catching disease, so that the reasons which have led to the free distribution of diphtheria antitoxin and salvarsan do not apply. Things which are to be had for nothing are generally used wastefully. The cost will rise progressively by the very success of the treatment in prolonging the lives of diabetics. Contrariwise, it is the business of the State to preserve its lives and to recognise that it is a paying proposition so to do. The public is entitled to enjoy the benefit of discoveries which have been made wholly or in part with the aid of public funds. Monopolies are held conditionally on no one being injured by their existence. Such and such are the pros and cons which are bandied about for dialectical exercise. The medical profession will recognise that they are almost wholly beside the point. The entire hospital system is a plain monument to the ideal that the sick have a call on the service of the sound, that the needy are entitled to the help of those who have what they require, and that those who are sick as well as needy are a charge upon everyone. So long as mankind clings to its immemorial axiom that life on any terms is better than no life at all, it will be unthinkable that a potent and valuable remedy should, as a piece of actual practice, be withheld from anyone merely because he has not got enough money to pay for it. The public notoriety which has been achieved for insulin makes it particularly impossible that it should be left as a class remedy. There were inhumanity and disappointment and pain enough through the period when everyone with diabetic children and friends knew all about it and very few could get it. Now that it is available in ample amounts, there ought to be no more difficulties. Whether free insulin should be supplied by some analogue of the Surgical Aid Society or by the public authorities is a minor question of technique. There is not so much difference between the two nowadays, and the State seems to be the obvious and simple medium. But the guiding principle is clear. It is the motto of Guy's Hospital—*dare quam accipere.*

THE HISTOLOGICAL STUDY OF NEOPLASMS.

RECENT developments in the experimental study of the origin of tumour growth have in great part diverted attention from the results of the traditional lines of investigation rendered illustrious by the work of Waldeyer, Virchow, Cohnheim, and Ribbert. Dr. G. W. Nicholson's studies in tumour formation, of which No. VII.[1] has just appeared, come as a useful reminder of the prime necessity of accurate histological work as the basis of knowledge in all cellular problems. Dr. Nicholson has come to the conclusion that tumours arise in displaced or dislocated cells or cell-groups of the tissue of origin, and in Study VII. extends this conception to the heterotopic new growths in which the histological differentiation departs from that of the surrounding organ. With an extensive and exact knowledge of the literature and a skilful choice of well-executed figures the author marshals the evidence to the conclusion that the heterotopic tumours arise from normally differentiated cells by an intrinsic transformation of which there are many examples apart from tumour growth. Without abating one jot of our admiration for the author's painstaking devotion to a laborious specialty, it is permissible to venture the suggestion that the ultimate solution of the problems of neoplasia will come from a combination of the methods of descriptive and experimental pathology, rather than from their pursuit as separate disciplines.

CARDIO-VASCULAR COMPLICATIONS OF KYPHOSCOLIOSIS.

DR. Ernest P. Boas,[2] medical director of the Montefiore Hospital for Chronic Diseases, New York, who reports an illustrative case with a review of the literature, remarks that the functional disturbances of the respiration and circulation connected with kyphoscoliosis have not received the attention to which they are entitled. Although the frequency of dyspnœa in such patients was known to Hippocrates, Bouvier in 1874 was the first to show that dilatation of the right chambers of the heart was a very frequent finding in scoliosis. The most complete investigation is to be found in a monograph published in 1899 by Bachman, based on 197 personal cases of scoliosis or kyphoscoliosis which came to autopsy, as well as 79 cases recorded in the literature. Of the total 276 cases 247, or 89·5 per cent., presented an organic lesion of the heart or pericardium, but only 13 had organic valvular defects. Among 154 cases in which the heart was examined more carefully to determine the nature of the hypertrophy or dilatation 87, or 56·4 per cent., had hypertrophy and dilatation of the right ventricle, 27, or 17·5 per cent., of the left ventricle, and 40, or 25·9 per cent., of both ventricles. Bachman also noted that displacement of the heart upward and in an opposite direction to the scoliosis was very frequent, giving rise to a tortuous and angular deviation of the aorta, the large vessels, and inferior vena cava. Of 195 deaths studied by Bachman, 116, or 59·4 per cent., were due to cardiac failure and 24 to tuberculosis. The usual symptoms are dyspnœa, due at first to pulmonary atelectasis and emphysema, and later to myocardial insufficiency, cyanosis, and œdema of the legs. Attacks of palpitation and pain may occur in crises. The pulse is not infrequently rapid and may be irregular. As the myocardial insufficiency progresses, dyspnœa, cyanosis, and œdema become more marked, the liver becomes enlarged, the excretion of urine is greatly diminished, and anasarca and ascites may ensue. The prognosis in patients with kyphoscoliosis depends mainly upon the reserve power of the heart. It is unfavourable when once the signs of myocardial insufficiency are established, and the end is frequently precipitated by intercurrent pulmonary affections. Dr. Boas's patient was a woman, aged 29, in whom scoliosis was first noted at the age of 9, and had slowly and progressively become worse. For 10 years she had suffered from attacks of giddiness appearing every month, and for about five years from dyspnœa on exertion. Examination showed the case to be one of paroxysmal auricular fibrillation with symptoms of myocardial insufficiency. The issue of the case is not recorded.

LIFE ASSURANCE AND SYPHILIS.

The bearing of syphilis upon life assurance is discussed by Dr. W. P. S. Branson in the current number of *St. Bartholomew's Hospital Reports* (vol. lvi., part 2.). Dr. Branson begins by inquiring into the incidence of syphilis among the insuring population, and comes to the conclusion that the best estimate is a figure of about 10 per cent. He then discusses the effects of syphilis as a lethal disease, and points out that it may kill as the result of (1) general paralysis of the insane, (2) aortic aneurysm, (3) gummatous disease of the cerebral vessels, (4) tabes dorsalis, (5) epithelioma of the tongue, implanted on syphilitic leucoplakia, (6) suicide. Dr. Branson admits that there are other causes—one of the most common is cardiac failure from syphilitic disease of the coronary arteries, and this probably increases the mortality amongst syphilitics to a large extent. The author next takes up the period at which syphilis produces fatal results and points out that general paralysis and aortic aneurysm cause death between 30 and 50, while tabes, when it kills, as a rule kills late in life. He is not impressed with cerebral syphilis as a cause of death, but the statistics of the American Life Offices showed that the mortality among syphilitics was very high the first six years after infection, and death was almost always due to cerebral syphilis. Dr. Branson next discusses the question as to whether treatment can cure syphilis. It is well known that syphilis has been cured by mercurial treatment as recommended by Jonathan Hutchinson, who noted the occurrence of a second primary chancre after such treatment, and cases have been described of second infections after treatment with arsenic; but it is probable that in the great majority of cases once syphilis has been contracted, whatever the treatment, it is always liable to recur. This is especially true when any secondary manifestations of disease have developed. Dr. Branson does not place extravagant confidence in a negative Wassermann result. The blood test may be negative whilst the cerebro-spinal fluid is positive, and it is no uncommon event for the blood to be negative to-day and positive in six months' time. He says, however, that he considers a positive W.R. as a bar to life insurance. While agreeing with Dr. Branson that a negative W.R. is of no value as evidence of a permanent cure of syphilis, we are not so sure that a positive W.R. should be a total bar to life assurance. In a recent case a proposer, who had been perfectly well for seven years after contracting syphilis, was found to have a positive W.R., and in his anxiety to turn it into a negative one he had no less than 20 injections of neo-salvarsan in 12 months, the W.R. continuing positive, though he himself was in good health. Dr. Branson draws up rules as to the eligibility for insurance of lives who have had syphilis, and comes to the conclusion that those who have exhibited tertiary lesions, who have Argyll Robertson pupils, or leucoplakia of the tongue are ineligible, while increased rates must be charged for those who have had secondary manifestations and have been thoroughly treated for three years or more. He considers those who have been thoroughly treated in the primary stage and can produce evidence of negative W.R. three years or more after contracting the disease may be taken at ordinary rates. Some experienced observers would not entirely exclude cases of tertiary skin lesions, as many of these cases often live to a very considerable age. But all cases, even those giving a history of a primary sore only, should, we are convinced, be rated up.

EDIBLE FUNGI.

The latest publication of the Natural History Department of the British Museum is a Handbook of the Larger British Fungi,[1] by Mr. John Ramsbottom, M.A., F.L.S., assistant in the Department of Botany. Types have been selected for description on the ground of their economic and biological interest. In dealing with the fleshy agarics the basis of selection has been the edible or poisonous qualities of the species, the term "edible" being used simply to imply that the fungus has been eaten without ill effects. In this country only the field-mushroom (*Psalliota campestris*) and the horse-mushroom (*P. arvensis*) are commonly eaten, and for most people the cultivated variety of the field-mushroom is the only edible fungus. Mr. Ramsbottom expresses regret that this is so, for many of our common toadstools are far more delicate in flavour than either of these. This conservatism of taste is a modern failing. Classical literature contains frequent reference to various edible and poisonous fungi, and the only way in which to know whether a fungus is edible or poisonous is by being able to distinguish it in the same way as one does other edible plants and to ascertain its record. *There is*, says Mr. Ramsbottom, *no other way;* and his handbook will serve its purpose if it popularises the safe use of a number of cheap and appetising food products. The edible fungus contains roughly 2 to 5 per cent. of protein nitrogen (of which probably not more than one-third is digestible), 5 per cent. of sugars, 1 per cent. of fat, and ½ to 1½ per cent. of mineral matter. With this composition, fungi are a complete food, a fact established by the Fuegians, who live on *Cyttaria* during a large part of the year. In Central Europe, where the use of fungi as food is much more widespread, coloured wall charts are posted in the elementary schools, so that children learn from an early age the distinguishing marks of the poisonous and non-poisonous varieties.

VALUE IN DISINFECTION.

The Brazilian National Department of Health has reprinted an article from the Boletim Sanitario, No. 2, of 1923, with the view of impressing upon medical practitioners the futility of terminal disinfection in the prophylaxis of infectious disease. The gist of this article is that chemical disinfection of premises in which infectious cases have occurred can be of little value, seeing that the micro-organisms whose destruction is desired by that procedure are in number and virulence far less dangerous than those scattered through direct human agency or by means of recently infected articles. Moreover, many of these micro-organisms escape destruction by any means of terminal disinfection, whether by formalin spray or by disinfectant solution. Finally, the point is made that the employment of terminal disinfection on a large scale in all civilised cities has not diminished the infectious disease rate unless other prophylactic measures were simultaneously enforced. For these reasons, and on account of the great cost of chemical disinfection, the Brazilian Department of Health recommends the substitution for terminal disinfection of the simpler and less costly procedures of soap and water, scrubbing, and prolonged isolation and airing. In the case of dirty and dilapidated premises the usual measures of renovation are needed in addition. The Department holds that the suppression of chemical disinfection will have a good effect on the conduct of ignorant people who commit every sort of hygienic indiscretion in the course of infectious disease, confident in its redemption by the miraculous properties of the disinfectant apparatus. "People, not things, are the principal means for the distribution of disease germs, and simple measures of personal cleanliness have enormous prophylactic value." We have gladly summarised the contents of this estimable bulletin, the teaching of which coincides in a remarkable way with the lesson drawn this week by Dr. K. Simpson, deputy medical officer of health for the county borough of Croydon, from the figures in regard to scarlet fever which have come under his immediate notice. Dr. Simpson regards as a worthy object of effort the creation of a healthier state of the naso-pharynx in school children. We recall attention to a recent decree of the Prussian Ministry of Health pointing attention in the same direction.

THE SEDIMENTATION RATE IN ACUTE INFECTIONS.

THE rate of sedimentation of human blood shows considerable differences under various normal and pathological conditions. Thus the rate of sedimentation of woman's blood which varies from 3–5 hours is almost twice as rapid as in the case of man's blood. On the other hand, sedimentation of the blood of the umbilical cord is extremely slow and always takes longer than 24 hours. During pregnancy an acceleration of the sedimentation rate takes place and increases as pregnancy advances until delivery. In pathological conditions the sedimentation rate is most accelerated in inflammatory and febrile processes. The sedimentation rate is determined by estimation of the time required by the corpuscles of a specimen of citrated blood to sink from a certain marked level in a test-tube to another marked level. The sedimentation of the corpuscles is delayed by removal of fibrinogen, by narcotics, or by previously heating the plasma, while the addition of gelatin or gum arabic accelerates it. Dr. Mironesco,[1] of Bucharest, has investigated the rate of sedimentation of the red corpuscles in typhus, typhoid fever, and measles with an apparatus made according to the suggestions of Fähreus and Westergren. Pipettes were used 30 cm. long and 2·5 mm. in diameter, and a solution of 3·8 per cent. sodium citrate was employed to prevent coagulation of the blood. The examination was made 1, 2, and 24 hours after the blood had been collected at a room temperature of 20–25° C. In the three diseases mentioned Dr. Mironesco was able to confirm the fact that sedimentation was accelerated in a more or less marked degree. Fluctuations in rate were most pronounced in the course of the first hour. In typhus, for example, the rate of sedimentation was between 24 and 60 mm. during the first hour. The acceleration was less marked in cases of measles in the adult, in which during the first hour there was an oscillation between 11 and 20 mm. In typhoid fever the acceleration of sedimentation was usually more marked than in measles in the adult. It was also found that fluctuations in sedimentation bearing a direct relation to the severity and course of the disease occurred not only in the same disease but also in the same patient. Thus in a case of severe typhus which ended fatally the rate of sedimentation three days before death was 55 mm. during the first hour. In this case there were 2 g. of urea per litre of blood. In another case of typhus there was an oscillation between 30 and 20 mm. during the first hour, while the blood-urea was 0·90 and 0·80 g. In a case of typhoid fever with a pronounced ataxo-adynamic condition the quantity of blood-urea was 1·50 g. and the sedimentation 25 mm. during the first hour. With improvement in the patient's condition a diminution in the blood-urea took place, and the rate of sedimentation fell to less than half during the first hour (11 mm.). Dr. Mironesco concludes that there is nothing specific in the variations in sedimentation of the red corpuscles in various acute infectious diseases, for though the rate of sedimentation is usually more rapid in typhus than in measles or than in most cases of typhoid fever, the acceleration is related not to the particular disease but to certain disturbances, especially the amount of urea in the blood.

THE DECLINE OF VENEREAL DISEASE IN DENMARK.

IN connexion with the centenary celebrations of Pasteur's birthday, Prof. C. Rasch, of Copenhagen, was invited to contribute a paper on the subject of venereal disease and the campaign against it in Denmark. His small brochure, with the title "La lutte antivénérienne en Danemark," gives not only a very comprehensive review of what has been done in Denmark in the past, but it also shows what a remarkable effect modern methods of treatment have had on the incidence of syphilis in the years 1921 and 1922. With regard to the past, Denmark has certainly been a pioneer in many directions. So soon as 1672 the treatment of venereal disease by quacks was forbidden. In 1788 free hospital treatment for all cases of venereal disease was provided. As early as 1859 penalties were attached to the propagation of this disease, and ten years later its study was made compulsory for medical students. In 1874 compulsory treatment for all cases of venereal disease was introduced, and in 1900 Credé's method of dropping silver nitrate into the eyes of the new-born was made obligatory. In all these matters Denmark led the way, and in 1906 various other provisions were made for the comprehensive control of venereal disease. When Prof. Rasch was invited to give a survey of the results, up-to-date, of the venereal disease campaign, he, in coöperation with Dr. Svend Lomholt, addressed questionnaires to 130 heads of hospitals and similar institutions, and obtained information of great statistical value. It appears that the hospital accommodation in Denmark is greater than that of any other civilised country, and apart from sanatorium and asylum beds, Denmark, with a population of only 3,300,000, has about 14,300 beds, many of which are at the disposal of the subjects of venereal disease. But it seems to be rather ambulatory treatment with salvarsan and other specifics than hospital treatment that has brought the incidence of syphilis down with a run. In 1921 there were 1942 new cases of syphilis in the whole of Denmark, as compared with 1578 in 1922. The number of new cases of congenital syphilis in these two years was 142 and 95 respectively. In 1912 Dr. Lomholt investigated the number of recent cases of syphilis in Copenhagen, and he came to the conclusion that in this year there were about 1300 such cases. A comparison of these findings with those of 1922 led him to the conclusion that the incidence of syphilis had declined in this period by about 33 per cent. The evidence of these figures is supported by the impressions of most specialists with whom Dr. Lomholt has conferred, and it is noteworthy that the incidence of gonorrhœa has also shown a marked decline in the period 1910–1922. In the five-year period 1900–1904 there were 16 cases of blindness due to gonorrhœa, and in the ten-year period 1905–1914 there were only four such cases. Yet in other Continental countries about 20 per cent. of all cases of blindness are still due to gonorrhœa.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXXIV.

THE TREATMENT OF ANÆSTHETIC SICKNESS.

BY anæsthetic sickness I do not here mean the persistent vomiting, a symptom of formidable post-anæsthetic toxæmia or delayed chloroform poisoning, which has definite associated symptoms. This is a comparatively rare condition and is treated on well-known lines. The condition which concerns us now is, on the contrary, very common after any anæsthetic. It is one of discomfort and even misery for the patient, but being without danger and of comparatively short duration its treatment has not received much attention. Yet the nausea and retching, even without actual vomiting, that afflict many patients during the first 24 hours after taking an anæsthetic cause so much discomfort and may so prejudice rapid recovery that they are well worth the serious attention of the practitioner. From the patient's point of view these first hours after return of consciousness are a serious affair and anything that diminishes their discomfort is very gratefully received. Moreover, if a second operation on some future occasion becomes necessary it is often the recollection of the discomforts immediately following the first that prejudice a patient against facing the ordeal once again. It is highly desirable, then, that recovery from anæsthesia should not be synonymous with temporary misery. The means to achieve this end are preventive and curative. Preventive measures are mainly in the hands of the anæsthetist, curative measures depend generally more upon the surgeon or the practitioner. It must be confessed at the start that these means in both cases depend on empirical knowledge. We are ignorant of the exact causation of the discomforts that we are trying to prevent or to cure. We do not know the physiology of post-anæsthetic vomiting. We know a good deal from many thousands of clinical observations about the likelihood of post-anæsthetic discomfort or its improbability with various types of patient, and we know similarly the harmful effects of a meal too soon before the anæsthetic or per contra of too prolonged a preliminary starvation. But in many cases we do not know whether there will or will not be symptoms needing treatment after anæsthesia. Our treatment, therefore, both preventive and curative at present depends entirely on our experience.

Preventive Treatment.

This consists in (1) the proper preparation of the patient, and (2) selection of the most appropriate anæsthetic and method of administration for the particular patient. The preparation of the patient can be so overdone as to bring about more harm than good. With the ordinary healthy adult the less that his usual habits are interfered with the better. The operation should be arranged for a time about corresponding with that of a meal in the ordinary course of affairs, so that the stomach will be reasonably empty. An aperient should be given 36 hours before the operation time. The old practice of giving an enema an hour or two before operation is to be discouraged. The less the patient is interfered with shortly before the anæsthetic is given the better. If he is nervous or a poor sleeper a bromide draught should be given last thing on the night preceding the operation. Bromidia is a useful preparation for this purpose. During the 24 hours before operation the patient should be encouraged to drink water or some mildly alkaline mineral water between meals. Vichy water can be freely and comfortably taken by most people who consume three pints with benefit in the 24 hours. During the same period barley-sugar should be sucked often in order to supply the desirable amount of extra glucose. Meals should be of the kind to which he is accustomed, but the proportion of carbohydrate constituents—bread, sweets, and fruit—should be increased at the expense of the protein (meat) factors. One feature in the preliminary preparation deserves more attention than it usually receives. This is the search for and removal of any form of local sepsis. Thus the mouth should be carefully cleansed after every meal, the teeth and gums examined and dealt with by a dentist if necessary. The nose and antra should be inspected and should receive any treatment found needful. The septic patient is likely to suffer from after-sickness. Besides treating the local sources of infection the practitioner will improve his patient's prospects of a comfortable recovery after anæsthesia if he supplies some general treatment too. Dr. Nixon Groves, who has given much attention to this subject, uses the hypodermic injections of isotonic iron and strychnine (Fraisse) consisting of: cacodylate of iron, 0·01 g.; glycerophosphate of soda, 0·1 g.; cacodylate of strychnine, 0·005 g. He also has seen much benefit from the preparation of aluminium hydroxide known as alocol. When an operation is not one of urgency a week or two spent beforehand in eliminating all chance of sepsis and in perfecting the blood-state of the patient is time well spent in a way that will repay both patient and practitioner after operation.

If the operation is planned for the morning, about 9 o'clock, the patient is allowed a cup of tea as late as 7 o'clock if he is awake and desires it. At 8 he has a hypodermic injection of atropine gr. $\frac{1}{100}$. Whether this is combined with morphine gr. $\frac{1}{6}$, with omnopon gr. $\frac{1}{3}$, or with scopolamine gr. $\frac{1}{100}$ must depend on the circumstances of the individual case and no routine law can be followed. In the case of nervous women it is a good thing to add the scopolamine. Patients who are likely to require large amounts of anæsthetic should have omnopon or both this and scopolamine in addition to the atropine. As regards morphia it is wise not to give it before operation unless the patient knows from experience that it suits him. Some instances of sickness after operation are undoubtedly due to morphia. Atropine, on the other hand, may be used as a routine, and is an important element in diminishing sickness after ether. The use of this drug and the abandonment of closed apparatus during long operations have greatly reduced sickness after ether administration. Another valuable measure from this point of view is to ensure mouth-breathing throughout the anæsthesia. Patients who breathe through the nose under the anæsthetic, and particularly those with partially obstructed nasal air-ways who yet strive throughout to breathe through the nose, are much more liable to sickness after than those in whom the mouth is kept adequately open throughout anæsthesia. These patients, with deficient nasal air-passages and high narrow pharyngeal vaults, are in any case the most likely to suffer from protracted taste or nausea after ether.

As regards the choice of anæsthetic one is sometimes helped by a previous history to avoid the drug which has made the particular patient sick on a previous occasion. Generally speaking, when nitrous oxide and oxygen alone are sufficient for the surgical procedure they are by far the most likely to give freedom from after-sickness. They provide, of course, no such immunity when ether or C.E. mixture have to be added in the course of operation. Short operations under ethyl chloride are rarely followed by sickness or nausea of any length of time, though they often are by headache. So far as the anæsthetist's part is concerned in preventing sickness by his actions during anæsthesia the golden rules are: (1) maintain free mouth-breathing; (2) avoid cyanosis; (3) prevent swallowing of mucus or blood in operations where this enters the mouth; (4) keep the amount of anæsthetic given within the lowest limit compatible with perfect anæsthesia; (5) do not let the patient regain consciousness before he is back in bed, and see that he is moved gently. When in bed, if the operation permits, the patient should lie partly on his right side with the head on one pillow till consciousness has fully returned. After this the Fowler position can often be adopted with advantage.

Treatment after Anæsthesia.

This consists firstly in maintaining a quiet and darkened room. The patient lies with a towel moistened with eau de cologne or with vinegar laid over his face. Before consciousness has returned a rectal injection is given of half a pint of water containing 1 dr. of potassium bromide and ½ oz. of glucose, with 20 gr. of aspirin. By this means the drowsy period is prolonged, during which the elimination of the anæsthetic is completed and the likelihood of sickness is diminished. During the next 12 hours fresh fruit juice is the most suitable sustenance. Sucking pieces of fresh pine-apple relieves thirst, combats any unpleasant taste in the mouth, and supplies glucose. It is also for many people the most welcome and least nauseating form of nourishment during the early hours of recovery. Failing this, portions of orange may be sucked. If after consciousness has returned there is definite retching or vomiting a glass of water containing 1 dr. each of sodium bicarbonate and sal volatile is to be drunk outright. This must be repeated if necessary. In addition to this after abdominal operations, if there is distension as well as nausea, hypodermic injections of pituitrin in boiled water may be employed. An alternative measure which some have found successful is repeated administration of small doses of calomel. The practice of refusing absolutely to allow anything to be put into the stomach during the first 24 hours after anæsthesia does not meet with success enough to justify the extraordinary discomfort it inflicts on the patient. In some cases sickness is brought to an end by permitting some solid food in the form of cheese-biscuits or the like. In others there is presumably a nervous element in the causation, and the application of a mustard-leaf to the epigastrium is often successful, and so is placing the patient prone on his belly. If after 24 hours vomiting still goes on the stomach should be washed out with weak solution of bicarbonate of soda, and for 12 hours nothing should be given by the mouth, the patient subsisting on glucose and saline per rectum. It must be mentioned that crème de menthe has at times been found most successful in putting an end to post-anæsthetic nausea, and that a like success is often claimed for frequent small doses of iced champagne.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Women's Medical Education: New Madras School.

THE new Lady Willingdon Medical School for Women, Madras, was recently opened by H.E. Lady Willingdon. The new school will have its permanent habitation in the Victory Buildings on the Marina, but the opening ceremony was performed at the Victoria Buildings, Egmore, where work will be carried on until the buildings on the Marina are ready.

Lady Willingdon was received by Surgeon-General T. H. Symons and the Hon. the Rajah of Panagal, Chief Minister, who stated that the existence of a central institution for medical training of women had been long overdue in the province. The missionaries had recently brought into existence a Medical School for Women at Vellore, but the necessity for a central Government institution continued; financial considerations had hitherto hindered the Government from bringing it into existence. The school was now to stand by the side of the Queen Mary's College and the Madras Women's Training School, associated with first-class women's and children's hospitals; before long it was sure to be raised to the status of a college.

The pupils of the institution were presented to Lady Willingdon by Dr. Mary O'Brien Beadon, superintendent of the school. Lady Willingdon then declared the new building open.

Famine Code Revision.

Some months ago a committee was appointed by the Madras Government, in accordance with a resolution of the Legislative Council, for the revision of the provisions of the Madras Famine Code, 1914. The Government have now issued orders on the Committee's report and the following points are of medical interest:—

1. The Government have accepted the Committee's recommendation that the minimum age-limit of working children be raised from 10 to 12 years, and that the grain allowance for this class be 60 tolas (1 tola = 180 gr. troy).

2. The Committee recommended a reclassification of non-working children in the light of modern physiology. Formerly there were only four classes: (*a*) in arms, (*b*) under 7 but not in arms, (*c*) under 10 but over 7, (*d*) between 10 and 14. The new classification of children recommended to and accepted by the Government, with scales of grain allowances in tolas, is as follows: (*a*) up to 1 year, 15; (*b*) over 1 year, under 5 years, 20; (*c*) between 5 and 8, 30; (*d*) between 8 and 12, 35; (*e*) between 12 and 14, 45.

3. As regards the scale of wages and allowances to adult workers the Government, after careful consideration, concluded that a general revision of the scale is not called for.

4. The Committee's recommendations relating to the treatment of pregnant women, which were supported by medical opinion and were accepted, were, briefly, that rest is essential both before and after confinement—one month before delivery, and six weeks or such longer period as the medical officer may consider necessary after delivery; and that these women should receive during these periods of rest the full wages of workers, not merely the allowance of dependents, and that the allowance of R.1 for medical comforts should be increased to Rs.2 in view of the rise in prices.

The Government have in other respects accepted a large number of the Committee's recommendations. The revision has considerably improved the Madras Famine Code.

Ankylostomiasis Campaign in Madras, 1922.

The Madras Government have recently issued the report of Dr. W. H. Kenrick, director of the ankylostomiasis campaign for the year 1922. The campaign in Madras was initiated in the early part of 1920, when, upon invitation, the International Health Board lent the services of one of their officers. Dr. Kenrick had recommended during 1921 an extension of the work in several directions, including wider publicity, control measures in tea and coffee estates for a prolonged period, practical demonstrations and control measures in schools, and field studies of the stool habits of the people with the object of devising acceptable measures to stop soil pollution. This plan of work was sanctioned early in 1922, and before the end of the year the field staff had been increased to four sub-assistant-surgeons. The intensive work begun in North Arcot district was continued throughout the year, and in addition gratifying results were obtained on several tea estates in the Anaimalai Hills. A laboratory was opened in the General Hospital, Madras, where all persons admitted were examined, and the sub-assistant-surgeon in charge was also ordered to treat and instruct as many as possible of the inhabitants of the city. One interesting piece of work was done in the Medical College, Madras, where specimens were collected from 798 students and examined for hookworm. Over 80 per cent. of the students were found infected. A campaign was also conducted in a number of schools and factories with excellent results, while an infection survey commenced in Kistna district early in November was completed in December. No definite opposition to the work was experienced, but it was often very difficult to get specimens collected, except in schools and hospitals or where large numbers of labourers are employed. The attitude of employers of estate labour was not encouraging. Attempts to secure latrine construction in villages have so far proved futile. In June, Government issued an order requesting presidents of district boards of those districts having a district health officer to report through the Director of Public Health the steps they proposed to take for the control of hookworm infection, and similar reports were requested from the presidents of other district boards and chairmen of municipal councils in September, 1922. Summaries of the replies of 17 district boards and 59 municipalities have been prepared; 15 chairmen of municipal councils reported that hookworm did not exist in their municipalities or that hookworm was not prevalent and that it was not proposed to take any steps. In reply to this, surveys were undertaken in a number of places, and at Bezwada, for example, 1239 persons were examined and 1049, or 84·6 per cent., were found infected; in Masulipatam 90·6 per cent. of those examined were found infected. It has not been possible, of course, to conduct surveys in all towns and districts where local authorities denied the existence of hookworm, but these instances prove the necessity for an educative campaign. This mistaken idea is shared by people all over the province, and it is very important that microscopic examinations and worm counts be made early in as many districts as possible, so that specific knowledge of the incidence and severity of the infection may be at hand when it becomes possible to devise means for its control.

The total number of treatments given during the year was 49,916; of these 30,672 were first, 18,781 second, and 463 third or subsequent treatments. The drugs used were thymol, beta naphthol, oil of chenopodium, and carbon tetrachloride. Only a small quantity of the latter drug was obtainable and about 1000 doses were administered. The results obtained with carbon tetrachloride were most satisfactory. A few complaints of giddiness, headache, and slight burning in the stomach were received, but beyond these no objective or subjective symptoms arose. Oil of chenopodium found most favour with the masses. One fatality occurred which was probably a result of poisoning with oil of chenopodium: A very severely infected child of 6 years of age was treated with chenopodium and in the afternoon became sleepy and listless; during the night it fell into a state of coma and died early the following day. Three patients treated with an undivided 40–50 gr. dose of thymol completely collapsed, but all revived when given injections of strychnine, and were able to walk home within three hours. Dr. Kenrick considers that an undivided dose of 50 gr. of thymol, either with or without a purge, is not safe, and even a dose of 40 gr. may produce alarming symptoms in apparently strong healthy adults.

With regard to soil pollution the report contains some very pungent remarks. One public latrine for each 22,000 inhabitants in an area populated by 45 millions of people indicates conditions in the Presidency, and soil pollution occurs to as great an extent in municipalities as it does in rural areas. Dr. Kenrick considers, however, that soil pollution is not solely a result of an insufficiency of latrines, because in many places there are latrines which are never used. The people require to be taught that such things exist and what purpose they serve. A scheme is now being devised in Madras for the extensive treatment of persons harbouring hookworms. Estimates are being prepared of the cost involved in equipping all Government and local fund hospitals and dispensaries with the necessary materials, and by the middle of this year it was hoped that free treatment for hookworm infection would be obtainable at any hospital or dispensary in the Presidency. The infection surveys previously mentioned are conducted in coöperation with local health officers and with medical officers in charge of hospitals, and during their progress every effort is made to start local campaigns of examination and treatment which will be continued by the local medical officers in charge. In connexion with the educational part of the campaign, 124 lectures were delivered to audiences aggregating 25,874. A cinema film "Unhooking the Hookworm" has also been exhibited in a number of places. About 100,000 pamphlets and circulars were distributed, largely in schools, during the year.

New College and Hospital at Vizagapatam.

The Rajah of Panagal, Chief Minister, Government of Madras, recently opened the new Medical College and King George's Hospital, Vizagapatam. In his address the Chief Minister congratulated the staff on the good fortune of securing the services of Mr. Henderson as principal of the medical college. The idea of establishing a separate headquarters and Government Hospital was that of Sir Alexander Cardew. The Chief Minister, after tracing the history of the College, said that the Andhra community need not be anxious about the inauguration of an Andhra University, now that the Medical College had come into existence, the latter being the chief and the most costly item in the starting of any university. The Andhra University would, therefore, soon be an accomplished fact. He then declared the Medical College open. The Medical School will remain in its present location for two years, by which time a pukka building will be constructed. During the opening of the King George's Hospital the Chief Minister pointed out that there were only 20,000 medical practitioners in the Madras Presidency, while there were not less than 40,000 practitioners in England and Wales. That was the justification for embarking on an expensive venture in days when retrenchment was the cry everywhere. One of the criticisms levelled against the proposal was that Ayurveda should be encouraged, but the establishment of the new hospital would in no way obstruct or hinder the progress of indigenous medicine.

Madras, August 1st.

BERLIN.

(From our own Correspondent.)

Prophylaxis of Measles.

Dr. Degkwitz, of Munich, recently reported that in 175 cases of children undoubtedly infected with measles he has been able to prevent the disease from developing by giving injections of serum taken from convalescents. The efficiency of the method was proved in hospitals, creches, and orphan asylums, and also in private practice, by the fact that children living under the same conditions, in whom no injection was made, caught the disease. Of the cases receiving serum some were injected from the second to the third day of incubation, some on the fifth and sixth day, and the remainder still later. In the first series of cases a dose of 20 c.cm. was injected, but later it was stated that 3 c.cm. were just as efficacious. A smaller dose than 3 c.cm. did not prevent infection, but greatly weakened the virulence of the disease; prodromes and complications were absent, the exanthem was rather pale, and the fever was of short duration. Injections after the seventh day of incubation had no effect on the development or severity of the disease. The lasting efficacy of the serum was shown by the fact that injection of serum of adults who had had measles when young distinctly reduced the severity of the disease. The serum must be taken from the convalescent on the seventh day after the cessation of fever, when the blood contains the greatest quantity of antibodies; 40 c.cm. are taken from a vein of the arm, giving about 17 c.cm. of serum, to which are added a few drops of a 5 per cent. solution of carbolic acid. The serum is then preserved in ampoules. Degkwitz insists on the importance of preventing young and weak children from catching the disease, and states that the latter is not so harmless as it is believed to be by the well-to-do classes, in the Children's Hospital at Munich the general mortality from measles being 15·1 per cent., rising to 28·8 per cent. in children under 2½ years of age. The Government Medical Department has already taken steps to procure the serum for professional use; it will be prepared in children's hospitals and stocked in municipal health offices, and will be issued to medical officers of orphanages, creches, and similar institutions, and also to general practitioners. The department invites the profession to assist the work by notifying cases of convalescent children in order that the serum may be taken from them, provided the parents do not object.

Medical Men and the Profiteering Act.

The Act dealing with profiteering threatens with heavy penalties and imprisonment every person who charges for necessities a price out of proportion to the cost plus a reasonable profit. This law, which hitherto applied only to the sale of foodstuffs, clothing, &c., will now be extended to the charges of medical men among others. The new provision has created great indignation among members of the medical profession. The Act has already passed its first reading; the Leipziger-Verband has asked the Government to proceed no further with it, pointing out that patients are unable to estimate a doctor's difficulty and expense connected with any given case, and will, no doubt, be very ready to inform the public prosecutor if a fee seems to be too high. The Leipziger-Verband claims that the medical profession has always shown great unselfishness in its dealings with pauper patients, and that the Workmen's Insurance Act, under which they receive inadequate pay, would not work without their assistance. They consider it degrading to be threatened with fines for misdemeanours to be classed with those of grocers, tailors, and store-keepers who have charged too much for their goods. If the new clause is not withdrawn, they demand a provision to the effect that the public prosecutor may not take action against a medical man without having previously asked the opinion of the local Medical Chamber concerning the adequacy of a doctor's fee. It is, of course, feared that without some such provision a wanton or spiteful accusation from some disappointed patient may ruin the reputation of a medical man. The Minister of Justice has replied to the effect that, as the Act has already passed its first reading, it is too late to alter its provisions, but that he will instruct the responsible officials to prosecute only in cases of unquestionable overcharging, and that in doubtful cases the opinion of a Medical Chamber will be sought.

Threatened Strike of Club Doctors.

Medical men engaged in club practice have complained that their club fees, already very small, are paid so late that they lose a great deal of their value by the progressing depreciation of the currency. Negotiations with the club boards having led to no result, the Association of Club Doctors decided to strike; August 1st was fixed as the date of commencement of the strike, and arrangements were made so that from that date no difference of fee between private and club patients would be allowed—that is to say, that payment from club members would be required at once and on the same scale as from private patients, and that certificates for sick pay would only be issued by the medical men after payment (according to the existing agreement the latter payment is included in the consultation fee). In order to help the club doctors the medical faculty gave orders that during a strike no patient belonging to a club should be attended at a university clinic, and the same regulation held in out-patient departments of the Berlin hospitals. The Government Medical Department, anxious to avoid the great harm to public health which would have resulted from the strike, offered to arbitrate; the offer was accepted by both parties to the dispute, and negotiations followed under the chairmanship of a member of the department. Finally, on July 30th, an agreement was made according to which the remuneration of medical men was to be paid weekly instead of monthly or even quarterly. The pre-war sum of 5 marks for every member of the club is to be multiplied at the time of payment by the index figure representing the increase of the cost of living. The demand that the clubs should pay additional fees for the use of instruments, electric light, &c., was not conceded, being postponed for further consideration. The strike was thus avoided at the last moment. It may be remarked that pharmacists are also preparing to strike on account of late and irregular payments by the clubs; they announce that failing more rapid payments they will henceforth require cash from club members before medicine is delivered.

Combating the Red Ant.

The biochemical section of the German Institution for Agriculture has drawn attention to the fact that large colonies of the red house-ant, *Monomorium pharaonis*, have in recent years settled in Germany. The insects not only invade pantries and provision rooms, but have also a predilection for sputum, pus, and blood, and are therefore frequently seen in hospitals. They creep into the mouth, nose, and ears of children, and in one case were even seen invading plate-cultures and cadavers in dissection rooms. Their destruction, though difficult, since they nest beneath flooring, is very important, owing to the possibility of their spreading contagious diseases. The Institution invites hospitals to notify them when the insect is observed, and will then advise as to means of destruction.

Insurance against Hospital Expenses.

The expenses for a stay in hospital have become so high for patients not belonging to a sick-club, that a disease requiring hospital treatment may sometimes entail the ruin of a household. The head of the Government Medical Department, Prof. Gottstein, has therefore suggested that for the middle classes private insurance against hospital expenses should be instituted. This has lately been done, a company called "Salus" having been established for the purpose. The insured have to pay a premium of 5 gold marks a year, for which sum the company covers the insured person to the extent of one gold mark a day, the expenses of the period in hospital not exceeding 13 weeks. The profits of the company are limited to interest at 6 per cent., and any profit in excess of this figure must be spent for purposes of public welfare.

Quality of the Milk in Berlin.

Dr. Bing has recently examined 100 specimens of milk supplied in Berlin, purchased from different shops, and has come to the conclusion that the liquid supplied was sometimes more like an emulsion of bacteria than a potable milk. The bacteria referred to were of pathogenic species; in two of ten specimens pus was present, the milk obviously coming from animals suffering from diseases of the udder. The interior of vessels serving for the transport of the milk sometimes showed a stratum of milk, casein, and fatty substances, forming an ideal nutrient medium for bacteria.

The Supply of Medical Books.

The decision of leading publishers to suspend the issue of scientific works has been expected for some time. These books have become a drug on the market, as the reading public for this kind of book no longer has any money to purchase them. Even the public and university libraries can no longer afford to do so. The Rockefeller Institution, which on former occasions had greatly supported German medical work by procuring foreign books and journals for German medical men, has made a further gift of a new series of six copies each of 400 British and American medical journals. According to a system planned by the "Notgemeinschaft" (THE LANCET, 1922, ii., 1245) two of the copies will be kept in the State libraries of Berlin and Munich, whilst the others will circulate among the libraries of German universities, at each of which they will remain for a maximum period of two months. To facilitate the circulation the universities are divided into four groups of five to six universities each, so that every university library has the respective journal at its disposition within one year of publication. The southern group of universities consists of Freiburg, Tübingen, Heidelberg, Würzburg, and Munich; the northern group includes Hamburg, Kiel, Rostock, Greifswald, and Königsberg; the eastern group Berlin, Halle, Leipzig, Jena, and Breslau; and the western group Frankfort, Giessen, Marburg, Göttingen, Münster, Cologne, and Bonn.

A Model Rontgen Institute.

Messrs. Siemens and Halske, the well-known electrical engineers, have presented to the city of Berlin a full equipment of a modern radiographical institute with all the modern apparatus, with an undertaking to replace any apparatus as soon as a new invention has made it obsolete. The medical department of the city, in accepting the generous offer, proposed the appointment of a leading radiologist, and asked the municipal council to bear the cost of installation in the Moabit Hospital, where the institute is to be established.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Elections.

ALTHOUGH the poll was taken on Monday the results of many contests are not yet available, as proportional representation requires time to work out. For the National University Mr. Michael Hayes, Prof. John MacNeill, and Prof. William Magennis have been returned. None is a member of the medical profession, but all took a keen interest in medical matters in the last Dail, and their return will facilitate the proposed scheme of medical legislation in the Free State.

Food Prices in Dublin.

Last November a commission was appointed by the Government to inquire into the high prices of foods which still rule in the Free State. It has now reported its inability to arrive at any practical conclusions. Not being possessed of statutory powers to compel evidence the commission found itself met by a unanimous refusal on the part of traders to give any assistance. Brewers, bakers, millers, grocers, spirit grocers, all refused to reply to questionnaires issued by the commission. On the other hand, the commission finds fault with the purchasing public in that more voluntary evidence was not brought forward. No reason is given, however, for the failure of the commission to employ investigators on its own behalf, and one cannot but think that a little more zeal on the part of the commission might have produced more tangible results. Enough evidence was obtained nevertheless to show that prices of some commodities in Dublin are inexplicable on any economic basis. Guinness's porter, produced in Dublin, costs more in Dublin than in London, Leeds, or Cork, or apparently than anywhere in the British Isles. The price of milk in Dublin, for example, is without precedent. On this point the commission makes its only definite proposal. They recommend that a commission with statutory powers of obtaining evidence should be appointed to inquire into the price of milk in Dublin and the possibility of establishing some more economic system of producing and distributing milk than at present.

Increase of Admissions at a Mental Hospital.

At the last meeting of the committee of the Grangegorman Mental Hospital it was reported that there had been an increase of 91 patients since last year. A letter was read from the Secretary of the Local Government Department suggesting that the committee should consider whether separate provision for chronic and harmless cases should not be made, and advocating the conversion of an existing building in the district as an auxiliary mental hospital.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt F. J. A. Dalton, C.M.G., to R.N. Hospl., Haslar, temp.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Comdr. W. B. Betenson to be Surg. Capt.

Surg. Lt.-Comdr. F. J. S. Heaney to be Surg. Comdr.

Surg. Lt.-Comdr. J. B. Ronaldson to *Vivid*, addl., for R.N. Hospl., Plymouth, addl., for 14 days' training.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: B. H. H. Spence (to remain secd.). W. B. Laird, R. Davidson, H. S. Blackmore, J. M. Elliott, F. R. B. Shrimshire, D. W. Bruce, W. L. Webster (Bt. Maj.), E. B. Allnutt, S. P. Sykes, H. C. Todd (Bt. Maj.), H. J. G. Wells, F. S. Tamplin, W. Stewart, and A. S. Heale.

Capt. T. P. Buist is restd. to the estabt.

The undermentioned to be Lt. (on prob.): F. J. O'Meara, W. B. F. Orr, and T. W. Davidson.

Temp. Capt. R. R. Law relinquishes his commn. and retains the rank of Capt.

ARMY RESERVE OF OFFICERS.

Maj.-Gen. O. R. A. Julian, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Maj. and Bt. Lt.-Col. A. J. Chambers, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ARMY DENTAL CORPS.

Lt. (temp. Capt.) G. W. Allen to be Capt.

ROYAL AIR FORCE.

Flight Lt. W. G. L. Wambeek is granted a permanent commission, J. J. Walsh is granted a short service commission as a Flight Lt., G. M. Mellor is granted a temporary commission as a Flight Lt., and F. K. Wilson is granted a short service commission as a Flying Officer and is seconded for duty at the Bristol Royal Infirmary.

INDIAN MEDICAL SERVICE.

Col. to be Maj.-Gen.: W. H. Ogilvie.

The King has approved the retirement of the following officers: Lt.-Col. C. E. Williams, Maj. H. S. Hutchison, Maj.-Gen. Sir C. C. Manifold and Maj. N. H. Hume, and of the resignation of Capt. O. Wilson.

REGISTRATION OF HEALTH VISITORS IN SCOTLAND.—The Scottish Board of Health announce the opening of a register of health visitors. Persons discharging on behalf of a local authority all or any of the duties of a health visitor under a scheme of maternity service and child welfare or of tuberculosis or otherwise, and also persons discharging all or any of the duties of a school nurse under a scheme of school health administration, may apply for certification and registration. Forms of application will be supplied by the Board, 121a, Princes-street, Edinburgh.

CANCER:

MEMORANDUM OF DEPARTMENTAL COMMITTEE OF MINISTRY OF HEALTH.

A representative committee was recently ppointed by the Ministry of Health to draw up a emorandum on cancer for the guidance of local uthorities. The constituent members were: Sir George ewman (chairman), Dr. C. J. Bond, Sir George uchanan, Dr. S. Monckton Copeman, F.R.S., Dr. ajor Greenwood, Prof. F. Gowland Hopkins, F.R.S., rof. W. S. Lazarus-Barlow, M.D., Dr. J. A. Murray, r. T. H. C. Stevenson, Dr. S. Wyard, Lieut.-Colonel . B. Smallman, M.D. (secretary).

The terms of the memorandum are as follows:—

haracteristic Features and Natural Course of Cancer.

In this memorandum the term "cancer" is applied a group of morbid conditions known to affect man nd lower animals in all parts of the civilised world. he members of this group differ widely in naked eye nd microscopical appearances. They also differ in e age of the individuals affected, in the rapidity ith which they run their course, and in their liability become generalised throughout the body. But ey all agree in that (i) they are manifestations of isordered overgrowth of some tissue of the body, i) they are at first local, (iii) they are not encapsuled, v) they progressively invade the deeper parts,) they readily undergo degenerative changes, i) they tend to become disseminated to distant parts the body, (vii) they lead sooner or later to the death the individual in the vast majority of cases.

From the standpoint of preventive medicine and ublic health administration, there is a conspicuous ntrast between cancer and groups of other morbid nditions, such as the acute infectious diseases or berculosis, for which the fundamental principles prevention are well established. From the mass of edical experience and literature on cancer, old and w, we have an extensive knowledge of its natural urse and pathological anatomy; from mortality d other records we know much about its occurrence d geographical distribution. But knowledge useful r its prevention is still far from complete. The root use or causes on which the occurrence of cancer pends remain obscure. We do not possess any ecific means of producing immunity against cancer, we have against small-pox, nor have we any specific eans of curing the disease analogous to quinine for alaria or arsenobenzol compounds for syphilis. all these directions much valuable research work s been undertaken, both within laboratories and tside them, and such research is being further rsued. Study with this object ought to receive ery possible support from central and local health thorities, from those responsible for hospitals and her institutions, from voluntary agencies, and from e general public.

Extent of Cancer Mortality and its Increase.

In a population of 37,885,242 persons in England d Wales in 1921, a total of 46,022 deaths were tributed to cancer. These figures imply that out each average million persons 1215, and out of each ousand 1·21, died of cancer. The death-rate per 00 of the population attributed to cancer in England d Wales has gradually increased from 0·32 in 51–60 to 1·12 in 1911–20, and 1·21 in 1921. To me extent this fourfold increase is due to the fact at a larger proportion of the population than rmerly is now of those ages at which deaths from ncer commonly occur; but when full allowance s been made for this ageing of the population, the crease is from 0·33 in 1851–60[1] to 0·97 per 1000 in 1911–20, and 1·01 in 1921, so that in the space of two generations the recorded mortality has trebled.

It has long been matter for discussion to what extent this increase has been due to improved diagnosis and more accurate certification of cause of death. There can be little doubt that these factors have been contributory, but unfortunately it has now to be recognised that they will not account for the whole of the recorded increase. Superficial cancers, such as those of the tongue or the female breast, were readily recognisable as such even 60 years ago, by the time death occurred. Yet in the 20 years' period 1901–21 (after making allowance for the ageing of the population) the mortality of males ascribed to cancer of the tongue has increased from 38 per million living in 1901 to 53 in 1921, and that of females from cancer of the breast from 148 in 1901 to 190 in 1921, increases of 39 and 28 per cent., respectively, in 20 years. During the same period the mortality, similarly stated, of the total population from all forms of cancer increased from 841 per million in 1901 to 1007 in 1921, or by 20 per cent. There is only one part of the body frequently attacked by cancer, the womb, in respect of which significant increase in mortality is not recorded during these 20 years—a fact which may in some degree be attributed to the fall in the birth-rate.

During this period of 20 years, from 1901 to 1921, in which cancer increased by 20 per cent., the general death-rate fell by 32 per cent., that of infants by 45 per cent., and that from tuberculosis by 38 per cent., while substantial declines were recorded with respect to most other causes of mortality.

An increase of mortality attributed to cancer is the common experience of modern civilisation.

The frequency with which different parts of the body are attacked by fatal cancer differs greatly in different countries; it may differ over a period of years even in the same country; and changes are occurring not only in respect of the parts of the body attacked by cancer, but also in regard to the ages at which deaths occur. In this country the tendency is for deaths from cancer to occur later in life than formerly, and this change has been going on, at least amongst females, for many years. The latest available returns show that the death-rate from cancer is not increasing for males up to 45 years of age, and for females up to 60. The most rapid increase is occurring in extreme old age.

Great differences in regard to the parts of the body attacked by cancer also exist between the sexes. The excess of deaths of females (over males) from cancer is entirely due to malignant disease of the breast and generative organs; in most other parts of the body a considerable excess is recorded for males. There is a great difference between the relative frequencies of different forms of cancer amongst married and single women. Cancer of the womb is more fatal to married and widowed, and cancer of the breast and ovary to single women. In 1911–20, for every 100 deaths of single women from cancer of the breast, there were 392 deaths of married women, for every 100 deaths of single women from cancer of the ovary there were only 272 deaths of married women, but for every 100 deaths from cancer of the uterus in the single women there were as many as 1009 amongst the married women. During this period there were 463 deaths of married and widowed for every 100 deaths of single women, so the excess of deaths for the married is much larger than normal in the case of cancer of the womb, but smaller than normal in those of the breast and ovary. The death-rates for 1911–20 corrected for age distribution are not yet available, but for the years 1911–13 we have the following figures, which are death-rates per million women living corrected for age distribution:—Cancer of the womb: Unmarried women, 169; married and widowed, 293. Cancer of the breast: Unmarried women, 346; married and widowed, 238. Cancer of the ovary: Unmarried women, 60; married and widowed, 31.

---

[1] Another way of presenting the facts is this. In 1851–60 e mean population living in England and Wales is estimated to ve been 18,996,916 of whom 60,196 (317 per million living r annum) were recorded as dying of cancer. In 1911–20 an estimated mean population of 35,750,765 the number of aths ascribed to cancer was 399,511 (1,117 per million living r annum).

Proclivity to Cancer.

The large majority of people go through life, even to old age, without suffering from cancer, but the geographical and social distribution of cancer mortality shows that the risk of being attacked by cancer is one which is widely disseminated. In a broad sense, liability to cancer is not an attribute of any particular social class, profession, or occupation. It is to be inferred, therefore, that the occurrence of cancer depends, to an important degree, on personal predisposing factors. For the purpose of this memorandum there would be no advantage in detailing or summarising studies or speculations on the nature of those factors, on the specific, general, or constitutional antecedents of cancer, or on the meaning of "proclivity" to cancer. Knowledge is not far enough advanced. It is right, however, to point out that *hereditary* predisposition to cancer has not at present been proved to be of any practical importance in man; that it cannot be asserted with scientific authority that the use of any particular article of food increases the liability to cancer, or prevents it from appearing; that no known drug or preparation will prevent its appearance or cure it when present; and that no danger of cancer has been proved to result from inhabiting houses or districts in which cancer happens to have been exceptionally common. There is no evidence to show that cancer is an infectious or contagious disease.

Chronic Irritation as a Determining Factor in the Appearance of Cancer.

One certain fact about cancer is that it frequently follows on chronic and prolonged irritation. Not all tissues, however, are equally liable in this respect. The palm of the hand, for example, in spite of its exposure to chronic irritation of all kinds, is probably never the seat of cancer. In the female breast cancer occurs far more commonly in the deeper parts of the gland than in the nipple, which is more exposed to injury. Some tissues show a special liability to develop cancer during chronic irritation, such as the skin of the face, the lips, insides of cheeks, tongue, lower part of bowel, neck of womb. Certain varieties of chronic irritation, too, are more liable to be followed by cancer than others. Thus, in the lip, long continued irritation by a clay pipe is particularly dangerous; in the tongue, irritation by a jagged tooth or badly fitting toothplate; in the womb, the chronic ulceration which may follow confinement. Again, syphilitic disease affecting the tongue or female external generative organs, or tuberculosis of skin (lupus) affecting the face, particularly if it has necessitated prolonged treatment, is liable to end in cancer. And lastly, workers in tar, such as briquette makers, workers with anilin or paraffin, chimney-sweeps, and mule-spinners are apt to suffer from cancer in special parts of the body as a consequence of repeated irritation by the particular agent concerned.

This liability of cancer to follow chronic irritation of so many different types is remarkable, and leads to the supposition that beneath them all there lies some common factor—as yet unrecognised—which is fundamental to the passage of a chronic inflammatory and non-cancerous condition into one that is definitely cancerous. In one variety of cancer (rodent ulcer) the distribution of the new growth is such that it suggests a close relationship with the nerve-supply of the affected part. How far this is true and how far modifications of the body itself as distinguished from the chronic irritant play a part in the ultimate production of the cancer it is impossible to say in our present state of knowledge.

Prophylaxis.

While considerations such as those in the section on Proclivity to Cancer show how far we are from being able to say how cancer is to be avoided, those under the heading of Chronic Irritation as a Determining Factor in the appearance of cancer indicate that there are at least some provocative causes of cancer which can be guarded against. Since cancer occurs more commonly in certain sites, it is prudent to notice an remove causes of chronic irritation in these sites Apart altogether from cancer, people should atten to these conditions in the exercise of common ca for their general health and fitness.

In this category, for example, and for reasons jus given, come the removal of rough stumps of teeth o replacement of badly fitting dentures; a change o habit if pipe-smoking is found to produce soreness o the same spot of the lip or tongue; an alteration o clothing which causes irritation of particular region of the body—for example, the breast; the avoidanc of constipation and other like matters. On the sam basis the possibility of establishing a chronic irritatio in a region liable to cancer gives an additional reaso for obtaining advice and treatment in disorders o the stomach, bowels, or womb. Finally, specia precautions, the nature of which is well known t those concerned, must be adopted in certain occupa tions (tar, &c.) known to entail superadded an specialised risks of cancer.

Diagnosis of Cancer.

For reasons that are indicated in the next sectio (Treatment) early diagnosis is of the greatest import ance. This means not only diagnosis of the actua existence of cancer, but, even more, diagnosis of th existence of abnormal conditions that are commo precursors of cancer. Cancer itself in its early stage is almost invariably unaccompanied by pain, and i sometimes painless throughout. This painlessness o cancer in its early stages is one of its most insidiou dangers, since it leads the patient to delay seekin medical advice. Were cancer as painful in its earl stages as toothache, there would be far fewer of thos pitiable cases in which the patient first seeks advic when the cancer has reached a stage beyond all bu palliative treatment.

Early diagnosis obviously depends upon coöperatio between the patient and the doctor. Medical advic should be sought at once, particularly if a tumour o lump is found in the breast, if an ulcerated conditio exists on the tongue, lip or skin which does not he in a few days, if there is persistent hoarseness, if mole or wart shows a tendency to grow, if blood o mucus is passed with the stools, if there is bloody o offensive discharge at other than the normal monthl periods, especially at the change of life or after it ha passed. Even with the greatest care and ski doubtful cases occur; but only after careful medica examination can it be decided whether such condition are or are not indicative of cancer, and those wh seek advice in these circumstances are taking a wis course quite apart from cancer possibilities. A abnormality is there, and whatever it is due to i should be treated and not nursed in secret.

Treatment.

If a person has not recognised that something i wrong—and such cases occur—nothing more can b said. But very many persons are aware that some thing is wrong, fear it may be cancer and put o consulting a doctor because they think that if cance be diagnosed an operation will be necessary. Quit apart from the facts that anæsthetics and antisepti have robbed operations of many of their terrors, an that many such cases would not be cancerous at al the chances of a patient must be better the earlie he or she comes under treatment. Most medica authorities believe that in cancer early operatio affords the best chance to the patient, although the would not feel justified in stating that all risk o recurrence is necessarily removed by operation, eve if undertaken in an early stage of the disease. Bu there is indubitable evidence that removal by opera tion, though ultimately followed by recurrenc enables many people to live a natural life in comfo for considerable periods, while in advanced cases suc removal may relieve or prevent prolonged sufferin There are many cases, moreover, in which cancerou growths have been removed once and for all, th patient has lived for years afterwards without recu

nce, and has ultimately died from an entirely
fferent cause.

And, lastly, evidence is accumulating that in some
rieties of cancer, and in some situations, radium or
ray treatment, or diathermy, carried out by expert
edical practitioners, offers at least as good a chance
the patient as surgery, without the attendant
sadvantages, and in other cases it may be tried
hen surgery is out of the question. *The essential
int is that the patient should not postpone or delay
eking competent medical advice, and, above all, should
t waste time or money by trying quack remedies which
best are useless, and at worst aggravate the disease.
any condition in which cancer is suspected, immediate
d decisive action is necessary.*

The actual prospect of length of life after measures
r the removal of cancer have been taken is not a
atter for dogmatising, but without question the
rlier these measures are adopted the better.

Local Health Authorities and Cancer Questions.

Propaganda.—Many local authorities, on the advice
their medical officers of health, undertake invaluable
propaganda" in relation to certain diseases by
ans of public notices, advertisements, broadcast
flets, lectures, cinemas and the like. The considera-
ns set out above show how greatly cancer differs,
regard to the applicability of these methods, from
isease such as small-pox, for which there is a sure
eventive to be proclaimed, from other diseases of
infectious class where individuals must be urged
take precautions for the safety of their fellows, or
m diseases such as the venereal group for which
ecial and gratuitous treatment is provided out of
public funds, and requires to be advertised.
ch caution is obviously needed in announcements
the public on cancer in order to avoid overstatement,
making of promises which are not warranted by
dence, or the production of needless and mischievous
prehension of cancer. If all this is realised, know-
ge of some of the main facts of cancer (negative as
ll as positive)—such as are indicated in this Circular
nay usefully be spread through the ordinary
ncies of public health departments, notably by
truction at welfare centres, by midwives and
ternity nurses,[2] and by social welfare workers. It
d hardly be added that it is important for the
dical officer of health in advising on these matters
enlist the counsel and assistance of other medical
n, whether specialists or general practitioners, in
area.

Facilities for Diagnosis and Treatment.—It is not
templated or suggested that there should be
ablished throughout the country a public cancer
vice, analogous to the services for tuberculosis or
ereal diseases, or that for treating acute infectious
eases. Even if such a service were considered
irable, it would be out of the question until other
tters, such as the improvement of undergraduate
l post-graduate medical education in cancer
gnosis and treatment, have been further developed.
t public health authorities, insurance committees,
rds of guardians, or other public bodies concerned
uld not feel discouraged from individual action
hin the competence of these bodies from assisting
securing better facilities for diagnosis or more
ctive treatment of cancer in the areas or institutions
ler their jurisdiction. It has, for example, been
gested that local authorities, in conjunction with
local representative bodies of the medical profes-
in suitable areas (acting through a special cancer
mittee or otherwise) might periodically undertake
view of such questions as the following, considering
ach instance whether steps could and should be
en to meet the requirements of the area and the
lical profession within it, and enlisting the help of
who are likely to be of assistance :—

1) Improving the local facilities for clinical con-
ations and for pathological examinations ;

(2) Improving the local facilities for cancer treatment (operative, or provision of X ray and radium apparatus), and considering the adequacy of arrangements for this purpose at hospitals, local institutions, &c., which serve the area ;

(3) Improving the facilities for transport of patients ;

(4) Arranging locally for post-graduate demonstrations, lectures, or courses on cancer for medical men practising in the area ;

(5) Arranging locally for the education of the public as indicated in the paragraph on propaganda.

Should such local medical consideration of cancer problems lead to applications for the assistance or coöperation of public health authorities as well as of voluntary agencies and individuals, the Minister is confident that these applications will be considered practically and sympathetically by those to whom they are addressed. The Department will be glad at any time to receive communications on the matters above outlined in cases in which it would appear that its action would be helpful or its knowledge of local progress in dealing with cancer questions might be increased.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the principal health statistics of 11 London boroughs taken from reports for the year 1922 :—

Name of borough.	Estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Chelsea	63,920	16·1	13·3	0·9	1·6	—	—	—	11·6
Deptford.. ..	114,100	23·1	13·8	1·4	1·3	3·4	—	—	3·0
Fulham	159,500	20·3	12·1	1·2	1·3	2·8	67	103	3·7

The lines indicate that the report did not give the information.

Chelsea.

Dr. Louis C. Parkes, whose impending resignation is announced, mentions in his report for 1922 that the borough council spent £965 in subsidies to the Chelsea Health Society, the Red Cross Babies' Nursing Home, the Chelsea Day Nursery, the Chelsea Branch of the Invalid Children's Aid Association, the Chelsea District Nursing Association, and to convalescent homes for nursing mothers, and his report shows the benefits accruing. Half of the amount of the subsidies is recovered as a Ministry grant. Unfortunately, the Babies' Nursing Home had to be closed in July on account of complaints of the noise of crying infants and it has not been possible to acquire other premises as yet. There were 40 deaths from influenza and 53 notifications of acute primary pneumonia during the first quarter. Sixty per cent. of the deaths from pulmonary tuberculosis occurred in institutions. There were two deaths from puerperal fever and ten from other diseases, &c., of pregnancy. Of the latter,

er to all midwives on registration, and includes questions on
er in women in their examination for certificates.

four resulted from miscarriage, one illegally procured, three were due to eclampsia, and one each to rupture of the uterus, contracted pelvis, and nephritis. None of these cases had attended the ante-natal clinic of the Chelsea Health Society. The borough council have purchased a site of 60,000 square feet on the east side of Hortensia-road on which to build three- and four-roomed flats. The Ministry have required that the frontage of the site on Fulham-road be offered for sale and not included in the housing scheme.

Deptford.

In view of the decision of his council to give the annual health report a wider circulation in the borough, Dr. Charles S. Thomson has seized the opportunity to provide in it a lot of useful information for the public. The report is illustrated with photos descriptive of the maternity and child welfare work, including pictures of breast-fed babies, a healthy contented-looking mother with her recently weaned fourteenth baby of 11 months old, the Princess Louise Infant Welfare Centre, and the Municipal Maternity Home with its grounds. The report contains interesting articles on the prevention of cancer, the insulin treatment of diabetes, the science of milk production, and the prevention of rheumatic heart disease in children in the preparation of which Dr. Thomson has received the collaboration of several well-known physicians. Dr. Thomson has made another new departure by addressing a letter to his colleagues in practice on the subject of chronic rheumatism, which has evoked some interesting replies as to its ætiology, prevalence, and treatment. His report should make good reading for the citizens who frequent the public libraries of Deptford. He compliments his council on their efforts re housing, but gives some terrible examples of overcrowding. The report opens with interesting comments on the recent census. The maternity home keeps full, and the endeavour is made to limit the admissions by means of the ante-natal clinic to normal cases and to find hospital accommodation for abnormal cases elsewhere. A tuberculosis care committee is actively at work; the secretary visits all cases before and after sanatorium treatment and the families during the patient's absence from home. A fund is badly needed to help families to tide over these difficult times.

Fulham.

Dr. A. Middleton Hewat submits his first health report for Fulham. During 1922 the Public Health Committee issued to the public leaflets on the early signs and symptoms of cancer. The tuberculosis work is handicapped by the lack of institutional accommodation for infectious cases. Thirty-one cases of puerperal fever were notified with only eight deaths, the low case-fatality being probably due to the excellent arrangement with the Fulham Guardians, by which suspected cases are admitted to the infirmary without waiting for absolute certainty of diagnosis. An outbreak of six cases of typhoid fever occurred in one house in July. The original case was probably of the ambulant type and prepared the food for the subsequent cases, but the mode of infection of the original case was not discovered. The tuberculosis care committee is able to do good work in arranging for the families of patients removed to a sanatorium, thanks to the excellent organisation of social work in Fulham. Six of the 642 samples of milk were coloured with annatto. Full particulars of the working of section 28 of the Housing, Town Planning, &c., Act, 1919, are given. This section gives the sanitary authority power to do work necessary to render a dwelling-house "in all respects reasonably fit for human habitation" in the default of the owner. The statement shows the great difficulties in which the sanitary authority become involved in their subsequent effort to recover the cost from the owner. The time given in the notice must be reasonable, the exact details of the work required must be given, the owner may apparently appeal to the magistrates at any stage on any point, even if he has neglected his primary right to appeal to the Ministry of
Health, &c. The Fulham Council have brought th
unworkable nature of the section to the knowledge
the Ministry and it is not surprising to learn that i
future they will only use this section in mo
exceptional cases.

Hampstead.

Dr. Frank E. Scrase reports that Hampstea
maintains its position as a healthy urban distric
Nevertheless it does not escape a high death-rate fro
cancer, a high mortality-rate among illegitima
infants, and, for 1922 at any rate, a high maternal deat
rate from childbirth. Dr. Scrase points out the ne
for an institution for advanced cases of consumptio
and for an open-air school for delicate and suspect
children. There is a representative tuberculosis ca
committee. The need for definite action regulating t
use of preservatives is emphasised. The Hampstea
Council do not do work in default of the owner und
section 28 of the Housing, &c., Act, 1919, but ser
notices on recalcitrant owners under the Publ
Health Act. Dr. Scrase points out that the comparis
of the census of 1921 with that of 1911 shows that t
density of population in the smaller-sized tenemen
is increasing, with the inevitable result of mu
undesirable mixing of the sexes after adolescence.

Kensington.

In his comments on the census, Dr. James Fent
shows that, while in the County of London there a
116 females to 100 males, in Kensington there a
159 females to 100 males, and in South Kensingt
more than twice as many females as males. T
cases of puerperal fever were notified with six death
and a determined effort is being made to get cas
removed to St. Mary Abbot's Hospital at an earli
stage of the disease. Cases will be admitted in futu
as "suspects" and the question of notification l
in the hands of the medical superintendent. Sin
April 1st, 1923, the whole of the tuberculosis work h
been centred at the North Kensington Dispensar
as it has been found that the Brompton Hospit
which formerly acted as the dispensary for Sou
Kensington, could not conveniently do the preventi
work in connexion with contacts, suspects, &
Dental treatment is provided for expectant a
nursing mothers at each of the seven volunta
infant welfare centres. The ante-natal centre open
by Queen Charlotte's Hospital authorities in Ju
1921, was attended by 1028 mothers. The sanita
control of houses let in lodgings is one of the m
difficult problems in Kensington. About one-fifth
the 27,000 houses in the borough are let in lodging
and these houses, originally intended for one famil
may now contain up to seven or eight families a
have undergone no special adaptation for t
purpose. The borough council are anxiously waiti
for the new by-laws for this class of house which ha
been under the consideration of the London Coun
Council for the last two years.

Paddington.

Dr. Reginald Dudfield's report contains a la
amount of interesting statistical information.
comparison between the triennium of 1910–12 a
that of 1920–22 shows a large increase in the mortali
of males aged 15–25, which is in marked contr
with the reduced mortality at other age-perio
Dr. Dudfield is convinced that child welfare wo
has reduced the mortality during the first year, b
that is not enough, he says, and at present no eviden
can be adduced to show definitely that the surviv
are reared with a good prospect of a healthy aft
lifetime. The cancer mortality during 1922 show
an unusual feature—viz., an increase in the male a
a decrease in the female rate, the figures being 1·
and 1·16 respectively. The ratio of homes of l
than five rooms to all homes at the last four cens
reports has been 63·2, 64·8, 70·2, and 77. Althou
there has been this increase in the proportion of sm
homes the density per room has decreased. Th
since 1901 the number of persons per one-room
house has improved from 1·83 to 1·60, per two-roo
house from 1·69 to 1·57, per three-roomed house fr

1·27 to 1·17, per four-roomed house from 1·15 to 0·95, nd per five-roomed house from 1·40 to 1·23. Like r. Hewat, Dr. Dudfield comments on the unworkbility of Section 28 of the Housing Act of 1919 or getting repairs done, and, like Dr. Fenton, he nxiously awaits the new by-laws for tenement ouses. No less than 18 out of 67 samples of milk aken at the G.W.R. terminus were found to be dulterated (26·9 per cent.).

Poplar.

Dr. Frederick W. Alexander's report gives the usual tatistics, including those of the three sub-districts f Poplar, Bromley, and Bow. During the year bout 56,000 gallons of electrolytic disinfectant fluid ere manufactured at a cost of 1*s.* per ten gallons. his is diluted to half strength before distribution. t is used for the three public baths in the strength f 1 part of chlorine per two million parts of water, he total amount supplied to the baths being nearly 000 gallons. During 1922 18,082 applications for ree milk were received, of which 16,215 were granted t an approximate cost of £8500. The report of the hief health visitor mentions that the mortality mong "toddlers" was very heavy. Comparing ith the previous year, the mortality during the econd and third years of life was more than doubled, uring the fourth year almost doubled, and during he fifth year slightly decreased. The increase is ccounted for by deaths from respiratory diseases in he early months of the year.

St. Marylebone.

Dr. Charles Porter in a foreword to his report escribes what is done to bring home to the individual he fact that hygiene is not all communal by means f various "weeks," such as Baby week, Health week, nd Rat week, by congresses, by lectures, by leaflets nd posters, and by the helpful coöperation of the ress. There are now only 12 cows kept in the orough. The borough council have on more than ne occasion represented to the Ministry and to the ondon County Council the need for the registration f premises, in which meals are provided or food is old ready cooked, or is prepared for sale, but up to he present no action has been taken by either of hese authorities. A case which was suspected to e typhus fever occurred in November, and was emoved to the North-Western Hospital. The usual recautions as to disinfection, &c., were taken, and o further case occurred. The patient recovered, nd the nature and cause of the illness remained bscure. At the end of the year, though a great art of the site for the Council's housing scheme had een cleared, the approval of the Ministry to the cheme had not been obtained. A liquid known as Fluid D" is being tried for the spraying of verinous premises, and up to now the results have been airly satisfactory. Dr. Porter's report opens with nteresting local information obtained from the ensus returns.

St. Pancras.

Dr. T. Shadick Higgins, who has now taken up is work at Capetown, submits his tenth and arewell report. The death-rate was higher than in he three preceding years, partly owing to influenza n the first quarter, and partly owing to measles, hich caused 100 deaths of children from January to ay. The census shows the unsatisfactory state of ousing. More than half the families live in teneents of one or two rooms. The dwellings occupied y one family number 9975, and those occupied by ore than one family 14,685. For the 56,653 families n the borough there are only 24,660 structurally eparate dwellings. The borough council dental linic for mothers and children at the British Dentists' ospital was continued. A weekly treatment clinic s held at the St. Pancras dispensary for mothers nd children referred from the centres. The council ake a grant of £500 in aid of the Mayoress of St. ancras home for ailing children under school age. overnment grants are received by 21 institutions n the borough, amounting, with the grant to the borough council, to over £14,000. An outbreak of scarlet fever occurred at the Foundling Hospital. There were 140 cases of mild type and no deaths. In view of other epidemics in the past and for every reason Dr. Higgins thinks the governors should carry out their scheme for removing the children to the country as soon as possible. The housing situation is perhaps the gravest problem in St. Pancras. Closing orders cannot be made. Underground sleeping rooms, formerly closed, are now in use. Dr. Higgins regrets the delay in dealing with the "truly awful conditions" in one of the unhealthy areas in Somers Town, but the Ministry state that in the opinion of the London County Council there are other areas even more urgently requiring attention, and suggest that the borough council might proceed without financial assistance from the State.

Southwark.

Dr. George Millson reports a higher death-rate than for the three preceding years, the deaths from influenza, measles, and whooping-cough all being numerous. Free milk was supplied to mothers and children at a cost of £2300. There is in Southwark a large number of labourers and unemployable persons, and the outlook is not promising in this respect, as many of the boys are not attached to a trade. Two cases of anthrax were notified, contracted from Chinese skins. Both were treated by excision and Sclavo's serum at Guy's Hospital and recovered. Measles is notifiable, and so is epidemic diarrhœa in July, August, and September. Nurses are engaged by the council to attend to these diseases. A municipal nursery was opened in January and had an average daily attendance of 40.

Westminster.

Dr. Francis J. Allan reports that the housing problem is slowly solving itself, many residents in Westminster having been enabled to move nearer their work in the suburbs. Although the Westminster Council has not built any houses recently, its contribution to the County Council scheme for providing 29,000 new dwellings (exclusive of those erected on cleared insanitary areas) during the five years from January, 1920, and to other building schemes in the metropolis amounts to £32,000 per annum. The Peabody Trust has completed nine blocks in Great Peter-street, with accommodation for 95 families, and when the Great Peter-street scheme is completed, a black spot will have been removed from the city. Reduction in cost has made it easier to get repairs done. Each of the last three decades shows an improvement in overcrowding, as judged by the "two to a room" standard. Thus the percentage of the population living more than two to a room at the four last census years was 37·1, 28·5, 21·7, and 15·5. Dr. Allan deals at some length with the addition of chemicals and preservatives to food. Fifty-four of 63 samples of peas, beans, and spinach contained sulphate of copper. The council prosecute successfully as a rule if the amount exceeds 2 gr. per lb., but last year two prosecutions, where this amount was exceeded, were dismissed by a temporary magistrate. Fifteen years ago Dr. Allan induced the French packers to restrict the amount of copper used, and he has now approached the Italian packers, who have newly taken to this business since the war, with a similar object. Two vendors were fined for selling potted shrimps containing 31 and 93 gr. per lb. of boric acid respectively. An informal sample of Russian caviare contained 21 gr. of boric acid per lb. and 7·5 parts of formaldehyde per 100,000. The matter was reported to the Ministry. Subsequent samples taken at Dover and Folkestone contained from 125 to 400 parts of formalin per million. Two consignments were seized at these ports and circular letters sent to dealers, restaurants, &c., warning them against purchasing caviare so treated. As regards preservatives, &c., in food, the Westminster City Council have expressed the view that a committee should be appointed to go into the whole question anew.

Correspondence.

"Audi alteram partem."

OPHTHALMOLOGICAL TRAINING FOR MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—Mr. Percy Flemming's letter in your issue of August 4th touches on a very important point. I agree that the time spent by the average medical student on ophthalmoscopy is practically wasted, in that the actual knowledge obtained will not be of much service in his practice. Even after 20 or 30 years of special practice it is quite possible to be in doubt as to fundus appearances. But, on the other hand, this is not the whole story. The examination of the fundus is not at first easy. The diffident student, if encouraged rather to attend principally to external diseases, may readily give up his place in the dark room to others and not bother about the fundus. But, once he has mastered the technique, this same student may quite possibly receive a stimulus which will make him an enthusiastic ophthalmoscopist for the rest of his life. Is it not, therefore, worth while after all to encourage rather than to discourage practice with the ophthalmoscope, even when one allows that the actual knowledge gained in the student's course is insufficient to enable him to diagnose and treat, in his future practice, unless he becomes a post-graduate student of ophthalmology?

I am, Sir, yours faithfully,
ERNEST THOMSON, M.D.

Stirling, August 18th, 1923.

THE IMPERIAL CANCER RESEARCH CAMPAIGN AND THE CANCER PROBLEM.

To the Editor of THE LANCET.

SIR,—I have just seen Dr. J. A. Murray's letter in your issue of August 18th. I am quite aware that the British Empire Cancer Campaign is distinct from the Imperial Cancer Research Fund, and I do not think my letter would lead anybody to suppose that they were identical. I am also aware that the latter has been in existence for 20 years, and that the former has not yet become established. My statement that the Treasury grant to the Imperial Cancer Research Fund is utterly inadequate would be quite correct if the word "Fund" were left out. That, of course, was my clerical error. I do not know who was guilty of the libel referred to in the last paragraph of Dr. Murray's letter. As far as I am concerned I never made such a suggestion or wrote anything that would bear that construction.

I am, Sir, yours faithfully,
Blackpool, August 22nd, 1923. LEONARD MOLLOY.

X RAYS IN EXOPHTHALMIC GOITRE.

To the Editor of THE LANCET.

SIR,—My experience of the value of X rays in the treatment of exophthalmic goitre, as recorded in my recent paper, has not met with universal acceptance. I can merely state that I have recorded my actual observations, and that it is quite possible that further experience may lead me to alter these views. It has been stated that the X ray treatment of my cases has been very badly administered as shown by the presence of scars, burns, and even of carcinoma. This is, of course, correct, but it is only fair to my colleagues at the London Hospital to explain, what was perhaps not clear in my paper, that these bad results were seen in cases that came to me because they were dissatisfied with the X ray treatment. They had come from all parts of England, and the X rays had been administered in many different clinics. Not one had received this treatment at the London Hospital. The fact remains, however, that although such treatment should be safe it is in practice associated with very grave dangers, which are likely to increase if the method is widely adopted. In the London Hospital clinic there have, of course, been no burns, but the heads of this clinic have not been at all satisfied with the results of treatment as applied to my second and third groups.

I am, Sir, yours faithfully,
A. J. WALTON.

Devonshire-street, W., August 20th, 1923.

SCHOLARSHIP IN MEDICINE.

To the Editor of THE LANCET.

SIR,—Sir Henry Morris has in an article on Scholarship and Medicine (THE LANCET, August 11th) called attention, seemingly with approval, to a letter in the *Times* in which I pleaded for a liberal classical preliminary education for medical students. I adduced the great names of Harvey, Sydenham, and Hunter in support of a freer, wider outlook—men who dealt with life as well as disease.

Sir Henry Morris and Dr. Peachey, in a reply to me revive and advocate as a scholar the name of a general practitioner—Francis Adams. I am content with their championship. But this excerpt is not uninteresting. Wickham Legg, writing of Samuel Gee and himself, says:—

> "We had both been brought up in what may be called the school of Francis Adams. The real Hippocrates could be distinguished from the pseudo-Hippocrates—the residue was unworthy of the father of medicine. The 'Aphorisms' were the right Hippocrates . . . and the other writings decided by their approach to the 'Aphorisms.' With some satisfaction Gee told me a papyrus had been found in which a list of his writings was given, and in the list were the treatises considered the most foolish of all."

I have trespassed on your space in my contention but may I quote from Gee?

> "The learned physician is almost extinct. I am sorry for it, because the rank which the profession takes in the world depends chiefly upon its physicians."

I am, Sir, yours faithfully,
RICHARD GILLBARD.

Willesden Green, N.W., August 26th, 1923.

A NATIONAL PATHOLOGICAL MUSEUM.

To the Editor of THE LANCET.

SIR,—With the recommendation made by Dr. E. H. Shaw in his letter in THE LANCET, August 18th, p. 364 I agree fully; a permanent museum of microscopic pathological specimens could hardly fail to be o service both for practice and for medical education I have elsewhere advocated that an exhibition o microscopic specimens be held with a view to clearing away the mystery that still pervades the pathology of the commoner malignant tumours of man. Although some recondite biological points are involved, the immediate causal agents are easily recognisable in certain common human cancers and sarcomas, and in the process important misconceptions in genera biology are corrected.

Results obtained by Carrel and Burrows abou thirteen years ago showed that in culture tissue cell live and multiply almost without limit; whereas in the body their life is relatively short. Carrel remarked on the presence of the characteristic cell inclusions &c., in his cultures of human cancer tissue, but he could not decide what they were. If mouse cance and Fibiger's rat cancer are the same disease as the common human cancers and sarcomas, they must contain the same cell inclusions, &c., in the same relation to the tissue cells. At present the diagnosi of cancer is histological, not causal, as is that o tuberculosis. Very different causes may produce anatomical changes that require close examination for their differentiation. In many human cancer and sarcomas, such as rapidly growing squamou epithelioma and large-celled sarcomas, it is easy to see that the cell inclusions are phases of protists, which account for about one-third of the weight of the tumours. If any doubt remained, examination of molluscum corpuscles in water cultures would clear it away.

I recommend the organisation of an exhibition of microscopic preparations of human cancer and sarcoma, and of cancer and sarcoma of rats, mice, and of birds; of molluscum, variola, and syphilis; of genital tumours of dogs, and of related lesions of animals and plants. Further, that in the exhibition space should be reserved for the demonstration, in water cultures of molluscum, of streaming, budding, and other vital changes in the corpuscles. I should be happy to show sections and other preparations that I have described from 1892 onwards, and to place published drawings beside the microscopes. Such an exhibition should be kept open for at least three months, and better for a year. In this way only can be created a wide educated opinion based on visible objects. At the close of the exhibition the more illuminating specimens could be selected to form part of a permanent collection such as Dr. Shaw has recommended.

I am, Sir, yours faithfully,

J. JACKSON CLARKE.

London, W., August 17th, 1923.

DIFFERENTIAL DIAGNOSIS OF SMALL-POX AND CHICKEN-POX.

To the Editor of THE LANCET.

SIR,—The outbreak of small-pox in England reported in your issue of June 23rd is of great interest from many points of view, particularly that of diagnosis. To some of us who live abroad in the midst of native communities small-pox becomes part of our everyday experience, and a note on the differential diagnosis of chicken-pox and small-pox as followed by the Asansol Mines Board of Health, Bengal, with very satisfactory results may be of interest to practitioners at home.

The Asansol Mines Board of Health was established by Bengal Act II. of 1912 (the Bengal Mining Settlements Act) to prevent "the outbreak and spread of dangerous epidemic disease" in the coal mines of Bengal. The "dangerous epidemic" diseases referred to are small-pox, cholera, and plague, the former two of which had up to the time of the passing of the above-mentioned Act taken such an annual toll of life of the mining population as seriously to imperil the continued existence of the mining industry. Plague is, however, unknown in the Asansol mining settlement, which is 413 square miles in area and ncludes 202 collieries, 491 villages, and the two municipalities of Asansol (population 21,727) and Raniganj (population 14,536). The total population of the settlement according to the census of 1921 is 329,353.

Under the Act every mine-owner and manager is bound to furnish to the Mines Board of Health "immediate information of any case or suspected case of small-pox, cholera or plague." This clause, however, was found in practice to be inoperative as ar as small-pox was concerned, since the majority of the Doctor Babus employed by collieries—on whom the duty of informing managers of the occurrence of such cases ordinarily devolves—persistently refused, either through negligence or ignorance, to recognise small-pox when it occurred, diagnosing all such cases as "chicken-pox" and thus avoiding the legal obligation of notifying the cases to the Mines Board of Health. It was therefore necessary to circumvent such ignorance and neglect of duty on the part of the Doctor Babus, and orders were accordingly issued by he Board that "all sickness accompanied by an eruption of vesicles" must be notified as small-pox. This order had the effect of securing the notification of all cases both of small-pox and chicken-pox as mall-pox, and it became necessary therefore to select f possible some easily recognised and constant diagnostic point of difference between the two diseases, to enable the sanitary inspecting staff of the Board—who possess no medical training—to report on inquiry the true nature of the disease, and to take the necessary steps to prevent its spread when the case was actually one of small-pox.

On studying the question it was found that it was universally agreed that the eruption of chicken-pox always appears within 24 hours of the onset of fever or malaise. This then was accepted for the use of the inspecting staff as the diagnostic test of chicken-pox, and as experience accumulated it was found that in a considerable proportion of cases the eruption appeared even before the onset of fever. All cases where a vesicular eruption appeared later than 24 hours after the onset of fever were ordered to be regarded as small-pox and steps to be taken for the isolation of the cases and for the wholesale revaccination and vaccination of contacts. On the form provided by the Board for the notification of small-pox two additional headings were then introduced—one being the "Date of onset of fever" and the other the "Date of outbreak of eruption," with a view to discover the usual time of eruption of the two diseases, and it was found on analysis of many hundreds of cases that the eruption either came out on the same day as the onset of fever or else did not appear until *after a well-defined interval* of at least 48 hours, no vesicular eruption ever appearing during the second 24 hours. It therefore became evident that two vesicular eruptive fevers existed, one characterised by an eruption appearing within 24 hours of the onset of fever or malaise, and the other by the non-appearance of any eruption until after the lapse of at least 48 hours. The former of these diseases, moreover, was constantly seen to have the diagnostic features of chicken-pox as described in the standard text-books, and the latter those of small-pox. In all cases, moreover, whether of chicken-pox or small-pox, there was to be obtained on careful inquiry from the patient or the relatives a definite history of fever, sickness, or malaise, however slight or fleeting, upon which to calculate the time of the appearance of the eruption. The time of the appearance of the eruption has therefore been adopted in the Asansol mining settlement as the crucial diagnostic test between chicken-pox and small-pox, and I feel no diffidence in recommending it to all those in doubt about the differential diagnosis of the two diseases.

In conclusion, I would add that an epidemic vesicular eruption unaccompanied by constitutional disturbance or physical disability of any kind may be safely left for diagnosis to the dermatologist and need not occupy the serious attention of the medical officer of health.—I am, Sir, yours faithfully,

J. W. TOMB, O.B.E., M.D., D.P.H.,
Chief Sanitary Officer, Asansol Mines Board of Health.

Asansol, Bengal, India, July 19th, 1923.

SPASM OF THE LARYNX.

To the Editor of THE LANCET.

SIR,—In the condensed report of the discussion on this subject in the Section of Laryngology and Otology (THE LANCET, August 18th, p. 359), I am credited with associating laryngitis stridulosa with rickets. I need hardly say that in this I am incorrectly reported, and that my insistence was on the well-known association of laryngismus stridulus ("spasm of the larynx") with rickets, and on its distinction from laryngitis stridulosa (sub-glottic laryngitis or common croup). My reference to the production of closure of the glottis and restoration of voice in some cases of functional aphonia by faradisation of the lingual tonsil was only apposite to the question under discussion in so far as it suggested a particularly sensitive "motor point" for the glottis-closers. It supported Mr. Mark Hovell's contention as to the rôle of the lingual tonsil in the production and treatment of spasmodic laryngeal cough. I am, Sir, yours faithfully,

London, August 22nd, 1923. JAMES DUNDAS-GRANT.

A DEFENCE OF THE FORAMEN OF MAGENDIE.

To the Editor of The Lancet.

Sir,—In The Lancet of June 9th, which has just arrived in Adelaide, is an article on the Choroid Plexuses of the Brain which, as is ever the case with the writings of Sir John Bland-Sutton, has a strong appeal to lovers of Hunterian anatomy. But I notice that, in speaking of the foramen of Magendie (p. 1145), Sir John Bland-Sutton says: "This foramen has had such charm for teachers that it maintains a place in text-books, although sealed up by practical anatomists many years ago." As a teacher I freely admit the charm of this foramen, and as a practical anatomist I also regard it with affection, for of its presence in the undisturbed condition of the roof-plate of the fourth ventricle I have no doubt whatever.

I am, Sir, yours faithfully,
F. Wood Jones,
Elder Professor of Anatomy in the University of Adelaide.
Adelaide, July 17th, 1923.

HEART DISEASE IN EARLY LIFE

To the Editor of The Lancet.

Sir,—The recent discussion on this subject by the British Medical Association (The Lancet, August 18th, p. 355) is valuable as showing grave divergencies of opinion with regard to the treatment of this important affection. One recommends the persistent use of salicylate "in the hope of preventing recrudescence of infection." Another says "treating rheumatism by pharmacopœial doses of salicylate is only playing with a serious disease." A third remarks "agreement was general as to the value of salicylate," whilst Dr. J. G. Emanuel, of Birmingham, holds that salicylate had not diminished the incidence of carditis.

Surely it is time that the profession were in a position to speak with authority on this matter, so as to prevent any further abuse by this powerful poison. Opium is valuable to relieve pain, but if relief of pain obscures symptoms at the same time, then opium is not a good drug. Salicylates relieve pain and reduce temperature, but is this all to the good? The reduction of temperature is at the expense of a very great blood disturbance, and the pushing of salicylates is responsible for many serious results. The time has arrived when a Commission should be appointed to investigate the whole problem of heart disease, and evidence taken from all parts, so as to determine once and for all the chief cause of this great national curse.

I am, Sir, yours faithfully,
G. Arbour Stephens,
Consulting Cardiologist, King Edward VII. Welsh National Memorial Association.
Swansea, August 20th, 1923.

REST AND EXERCISE IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of The Lancet.

Sir,—Following Dr. C. Lillingston's article on the Treatment of Early Pulmonary Tuberculosis in the Young Adult, published in your issue of Jan. 13th, much correspondence has arisen on the relative values of treatment by rest and by graduated exercise, on the whole to the condemnation of the latter. As far as the wage earner is concerned, the ideal of treatment is firstly to encompass the cure or arrest of the lesion, and secondly to fit the patient, both physically and mentally, to resume his original occupation. Immobilisation, as far as this can be effected in the case of the lung, is admittedly the first essential for the former end, but I submit that carefully graded exercise is almost as essential for the latter. In the case of working-class patients about three months of sanatorium treatment is usually allowed, but few patients can be graded in that time up to the standard of work they will have to perform when they are discharged, unless the patients are carefully selected cases and have been under efficient observation previously. A large number of working-class patients sent to sanatoria are not early cases.

Exercise is very difficult to graduate. The actual amount of work can be measured more or less accurately, but the effort necessary to perform it, and therefore, presumably, the degree of autoinoculation, varies with circumstances—e.g., atmospheric temperature, exposure to sun, previous aptitude for the type of work, &c. The doctor should supervise all the work of his patients, and, if he is able, should work with them. Patients appreciate this, and only in this way can he estimate the effort required to perform the work. Instructors can never replace the doctor, and are liable to be regarded by the patients as foremen whose business it is to get a piece of work done.

One doctor, if he acts in this way, can only supervise the work of a strictly limited number of patients, at the most 60. Most patients whom it has been possible to train and treat by graduated labour whilst in sanatoria are improved when they leave. Many subsequently relapse, because they return to the same conditions which were responsible for their breakdown, and they are probably unable to carry out the routine which they have been taught. In addition, many have to resume work which is far too strenuous, in order to gain some sort of livelihood, and even then are unable to procure sufficient food.

I am, Sir, yours faithfully,
Oxford, August 20th, 1923. W. E. Waller.

PENSIONS IN THE INDIAN MEDICAL SERVICE.

To the Editor of The Lancet.

Sir,—The fact that the more recent advertisements for recruitment to the Indian Medical Service differ vitally from those of the previous years does not appear to have attracted notice. The difference consists in the addition of a paragraph immediately after the "rates of pensions," which runs as follows: "The above rates are subject to revision after the 1st July, 1924, upwards or downwards, to an extent not exceeding 20 per cent."

As there is no probability of any revision *upwards*, it is perhaps a fair inference that pensioners must be prepared for a loss of 20 per cent. of their income after June next. Fortunately for an officer who entered the Service before July 1st, 1920, his pension will not in any case be reduced below that which he would have received under the old scale. This is a definite promise; vide India Office Memo., dated June 3rd, 1920. But what of those who entered after that date; whose pensions are not due, at the earliest, for another 14 years; and who have no promise beyond the text of the advertisement which attracted them and the regulations with which they were provided? How far down will the revision proceed, and what will be the value of a £400 pension in 14 years time? Of course, we all know, or should know, No. 1 of these regulations, which is as follows: "(1) The regulations are those in force at the present time. They are subject to *any* alterations that may be determined on." The italics are mine.

I am, Sir, yours faithfully,
August 19th, 1923. I.M.S. (retd.).

Alexandra Day at Brighton and Hove.—The Alexandra Rose Day collection on August 11th realised close on £1030, and after deducting the expenses (about £200) the remainder has been allocated as follows: Royal Sussex County Hospital, £300; Brighton, Hove, and Preston Dispensary, £85; Royal Alexandra Hospital for Sick Children and the Brighton and Hove Hospital for Women, each £77 10*s.*; Lady Chichester Hospital, the New Sussex Hospital, and the Throat and Ear Hospital, each £52 10*s.*; Sussex Eye Hospital and the Queen's Nurses, each £35; Surgical Aid Society, £17 10*s.*; Clayton and Keymer Nursing Association, £10; and the Brighton Dental Hospital, £5.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—E. N. C. Annis, Guy's Hosp. ; E. E. E. Attale, St. Thomas's Hosp. ; A. Cawadias, Paris ; H. S. Chadwick, Manchester ; H. T. Chiswell, Guy's Hosp. ; C. J. Fox, St. Mary's Hosp. ; K. P. Hare, Univ. Coll. Hosp. ; G. A. Lord, Manchester ; H. MacLachlan, Guy's Hosp. ; M. A. E. Somers, Bristol ; and J. N. Wheatley, London Hosp.

Medicine.—E. E. E. Attale, St. Thomas's Hosp. ; A. Cawadias, Paris ; J. H. Cooper, Glasgow ; J. B. Couche, Toronto ; J. Crawford, Royal Free Hosp. ; C. J. Fox, St. Mary's Hosp. ; K. P. Hare, Univ. Coll. Hosp. ; and M. S. Mahmud (Sect. II.) and W. R. H. Pooler, St. Mary's Hosp.

Forensic Medicine.—E. E. E. Attale, St. Thomas's Hosp. ; A. Campbell, Edinburgh ; A. Cawadias, Paris ; and K. P. Hare, Univ. Coll. Hosp.

Midwifery.—E. E. E. Attale, St. Thomas's Hosp. ; E. N. C. Annis, Guy's Hosp. ; A. Cawadias, Paris ; H. S. Chadwick, Manchester ; R. S. Chambers, Guy's Hosp. ; K. P. Hare, Univ. Coll. Hosp. ; G. A. Lord, Manchester ; Y. Nandan Lal, Dundee ; H. J. Powell, St. Mary's Hosp. ; and J. N. Wheatley, London Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery : E. E. E. Attale, A. Cawadias, H. S. Chadwick, and K. P. Hare.

CONJOINT BOARD R.C.S. ENG., R.C.P. LOND.: ADMISSION TO FINAL EXAMINATION.—These regulations have now been revised as follows, being slightly different from those given in the Students' Number of THE LANCET last week. Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Section I. of the Second Examination of the Examining Board, may enter for the Final Examination at the expiration of 30 months from the date of passing in anatomy and physiology on production of the required certificates provided they do not complete the examination before the expiration of five years of study. Members of certain recognised India, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subject of the First and Section I. of the Second Examination of the Examining Board may present themselves for the Final Examination under special conditions.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: PARKIN PRIZE.—In terms of the bequest made to the College by the late Dr. John Parkin, Fellow of the College, a prize is offered for the best essay on certain subjects connected with medicine. The subject of the essay for the present period is, in terms of the deed, "On the curative effects of carbonic acid gas or other forms of carbon in cholera, for different forms of fever and other diseases." The prize is of the value of £100 and is open to competitors of all nations. Essays intended for competition, which must be written in the English language, to be received by the secretary not later than Dec. 31st, 1923. Each essay must bear a motto, and be accompanied by a sealed envelope bearing the same motto outside and the author's name inside. The successful candidate must publish his essay at his own expense, and present a printed copy of it to the College within the space of three months after the adjudication of the prize.

UNIVERSITY COLLEGE HOSPITAL.—A festival dinner will be held on Nov. 20th in connexion with the Rockefeller Foundation Gift to the Medical School, when Prince Henry will preside. It will be remembered that the condition of the bestowal of the Rockefeller gift imposes heavy additional charges upon the hospital connected with the Medical School. The festival dinner is intended to inaugurate a campaign to raise £500,000.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Special courses in general medicine and surgery, cardiology, dermatology, diseases of children, ophthalmology, proctology, &c., have been arranged up to June, 1924. The programme for September will include a two weeks' course in general medicine and surgery at the Hampstead General Hospital in conjunction with the Hospital for Epilepsy and Paralysis, Maida Vale, the North-Western Fever Hospital, and Paddington Green Children's Hospital, from Sept. 10th to 22nd. There will also be a special course on infants' diseases at the Infants Hospital from Sept. 3rd to 21st, a course in ophthalmology at the Central London Ophthalmic Hospital, from Sept. 3rd to 29th, and a course in dermatology at St. John's Hospital for Diseases of the Skin, from Sept. 17th to Oct. 13th. For particulars apply to the Secretary, Fellowship of Medicine, 1, Wimpole-street, W. 1.

ST. MARY'S HOSPITAL.—The annual dinner of the past and present students of St. Mary's Hospital Medical School will take place at the Connaught Rooms, Great Queen-street, London, W.C., on Monday, Oct. 1st, at 7 for 7.30. Mr. V. Warren Low will be in the chair. The hon. secretary is Dr. Hope Gosse.

MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A work by Mr. M. W. Hilton-Simpson, entitled "Arab Medicine and Surgery," was published about a year ago, and reviewed in our issue of Oct. 7th, 1922 (p. 766). Mr. Hilton-Simpson has presented the instruments figured and described in his book to the Museum, where they are now on view. They were used by the Shawiya, a Berber tribe, living near Biskra.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—The following appointments have been made :—Consultant Physicians : Sir Malcolm Morris and Dr. James H. Stowers. Hon. Physicians : Dr. Wilfrid Fox and Dr. Henry MacCormac. Director of the Pathological Department : Dr. J. M. H. Macleod. Sir Malcolm Morris and Dr. Stowers have accepted seats on the Board of Management.

LONDON MEDICAL EXHIBITION.—This exhibition, the thirteenth of the series, will be held at the Central Hall, Westminster, S.W., from Oct. 1st to 5th. It will be remembered that admittance is confined to the medical profession, members of which resident within 50 miles of London receive cards. Other medical men desiring to take this opportunity of inspecting the exhibits in the medical, hygiene, dietetic, surgical, optical or dental sections can obtain cards on application to the Secretary at 194, Bishopsgate, London, E.C., or at the Central Hall during the exhibition week.

CANCER RESEARCH IN MANCHESTER.—In view of the recent gifts to the Christie Hospital for this purpose, announced in THE LANCET of August 18th (p. 367), it is interesting to record what has been done in Manchester in relation to the study of this disease. Mrs. Alfred Pilkington placed a sum of money in the hands of trustees to constitute the Pilkington Fund for this purpose, and in 1906 the systematic study of cancer was begun. The original sum has been supplemented from time to time. Dr. Charles Powell White was appointed to carry out research, and the University granted suitable accommodation for this purpose in the pathological department. In the deeds of foundation of the Christie Hospital, the investigation of cancer was one of the objects stipulated by the founders. From 1911 the stipend of the pathologist has been provided jointly from the Pilkington Fund and the Christie Hospital. In 1912 a legacy from Miss Helen Swindells enabled the University to equip a separate laboratory for cancer research, and to provide the expenses for its upkeep.

LAURA SPELMAN ROCKEFELLER MEMORIAL.—In our issue of August 18th (p. 345) we gave an account of the work of the Rockefeller Foundation. Another avenue of Mr. John D. Rockefeller's generosity, perhaps little known in this country, is the Laura Spelman Rockefeller Memorial, founded in October, 1910, in memory of his wife. The memorial is incorporated for general charitable and philanthrophic purposes, and is not limited geographically in its field of operations. The principal of the fund, as well as its income, may be used by the trustees in forwarding its humanitarian activities. The assets at the end of 1922 amounted to $78,074,773. During the period beginning with the Memorial's incorporation up to December, 1922, $9,361,871 had been paid on account of appropriations made by the trustees, and a sum of $3,486,888 awaits the fulfilment of conditions for payment. From 1919 to 1922 organised relief in Europe and China received a considerable proportion of the income ; non-secretarian social welfare organisations—the Y.M.C.A. and Y.M.W.A. in the United States, colleges in the Near East for education, &c.—received large sums. The various social welfare organisations during four years received over $3,299,345, while for education during the same period $801,222 were allocated. For scientific research and investigation—including the study of negro life and history, Bureau of Vocational Information, and Curie Radium Fund—$50,500, and for public health, which included contributions to many American institutions dealing with child hygiene, control of cancer, tuberculosis nursing, and maternity, $693,050 were spent during the last four years. The percentage of expenditure for public health will probably decrease in the future, not because the trustees are less convinced of the value of measures of public health in advancing human welfare, but because they feel that since the interest in and support for health enterprises are spreading widely, they may wisely turn their attention gradually to the development of less cultivated fields.

Donations and Bequests.—Mr. Robert Matthews, of Heaton Mersey, near Manchester, formerly a director of Sir Joseph Whitworth and Co., bequeathed £100 each to Carlisle City Infirmary, Newcastle-on-Tyne, Royal Victoria Infirmary, St. Mary's Hospital for Women and Children, the Pendlebury Hospital for Children, Manchester, Manchester Royal Infirmary, Dr. Barnardo's Homes, and Lord Mayor Treloar's Homes for Crippled Children.—Mr. R. Greenough, of Leigh, Lancashire, left £500 to the Leigh Infirmary.—The Manchester Children's Hospital during the past month has received donations and subscriptions amounted to £487.—The Ancoats Hospital Committee, Manchester, received £1009 as the proceeds of Daisy Days and the parade which took place in June. The Daisy Days show an increase of £281 over the figures for 1922. The Hospital Sunday Fund in aid of the Manchester and Salford Medical Charities realised £14,000; the principal grants apportioned are as follows: Manchester Royal Infirmary, £3569; Salford Royal Hospital, £1510; Ancoats Hospital, £1468; Children's Hospital, Pendlebury, £1362; St. Mary's Hospitals for Women and Children, £1327; Royal Eye Hospital, £1007; District Nursing Institution, £730; Hospital for Incurables, £706; Hospital for Consumption, £511; Memorial Jewish Hospital, £462; Northern Hospital, £315; and the smaller hospitals lesser sums in proportion.

Royal Medical Benevolent Fund.—At a meeting of the committee, held at 11, Chandos-street, Cavendish-square, W., 36 cases were considered and £285 18*s*. voted to 22 applicants. The following were new cases relieved:—

Daughter, aged 41, of M.R.C.S. who practised at Clifton and died in 1913. She started as a children's nurse in December, 1922; in June, 1923, it was found that her lungs were affected. She is now in a sanatorium and asks the Fund to help with maintenance. Her father died leaving a bankrupt estate. Voted £18 18*s*. for sanatorium treatment.

Widow, aged 64, of M.D., F.R.C.S. who practised in Staffordshire and died in 1891. Applicant has a little house property which brings in about 38*s*. per week and her rent amounts to 14*s*. per week. She has been suffering from diabetes for years and is now in hospital under treatment at £1 1*s*. per week. She asks the Fund to help her as she has to pay a debt of £194 incurred for sanitary work apart from doctor's and chemist's bills. Voted £10.

Widow, aged 74, of L.S.A., L.R.C.P. who practised in London and died after a short illness in February last. House and furniture had to be sold, and after mortgage had been paid and all expenses applicant estimates that her income will not exceed £35 per annum. At present her board and lodging costs 35*s*. per week. Voted £18 in 12 instalments.

Widow, aged 53, of M.B. who practised in Poplar and South Africa and died in 1912. Applicant, owing to physical inability, is unable to do private nursing continually. She has maintained and educated her daughter and is now hoping that her daughter will be able to secure a post. Applicant has received £86 from nursing, and pays 15*s*. per week for rent. Voted £10 in two instalments.

Subscriptions may be sent to the hon. treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE, SPECIAL COURSE IN INFANTS' DISEASES, at the Infants Hospital, Vincent-square, Westminster, S.W.

Monday, Sept. 3rd.—2–3.30 p.m., Dr. William Robinson: Summer Diarrhœa. 4.30–6 p.m., Dr. Eric Pritchard: General Principles in the Feeding of Infants.

Tuesday.—2–3.30 p.m., Dr. Eric Pritchard: Tuberculosis in Infants. 4.30–6 p.m., Dr. Helen Mackay: Demonstration, Lumbar Puncture, and Examination of Cerebro-spinal Fluids.

Wednesday.—2.30–3.30 p.m., Dr. Helen Mackay: After-effects of Diseases of the Central Nervous System. 4.30–6 p.m., Dr. Bertram Shires: Demonstration in X Ray Department; Diagnosis in Infancy.

Thursday.—2–3.30 p.m., Dr. Donald Paterson: Cases of Indigestion and Examination of Stools. 4.30–6 p.m., Dr. William Robinson: Respiratory Disease in Infants.

Friday.—2–3.30 p.m., Dr. Eric Pritchard: Round Table Consultation. Cases in Out-patient Department. 4.30–6 p.m., Dr. Donald Paterson: Lecture and Demonstration: Cœliac Disease.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Sept. 3rd.—10 a.m., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2 p.m., Mr. Addison: Surgical Wards.

Tuesday.—10.30 a.m., Dr. Paterson: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2 p.m., Mr. Sinclair: Surgical Out-patients.

Wednesday.—12 noon, Mr. Sinclair: Abdominal Surgery (Lecture). 2 p.m., Mr. Gibb: Eye Dept. 3 p.m., Dr. Pernet: Skin Dept.

Thursday.—12 noon, Mr. Simmonds: Demonstration of Fractures. 2 p.m., Mr. MacDonald: Genito-Urinary Dept. 3 p.m., Dr. Scott Pinchin: Medical Out-patients.

Friday.—10 a.m., Mr. Dudley Buxton: Dental Dept. 2 p.m., Dr. Burrell: Medical Out-patients. 2 p.m., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

Saturday.—10 a.m., Dr. Paterson: Medical Diseases of Children. .

Daily, 10 a.m. to 6 p.m. Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departs.

Appointments.

Armstrong-Jones, Sir Robert, M.D., has been appointed Consulting Physician to the Department of Psychological Medicine, St. Bartholomew's Hospital.

Cowan, A., M.B., Ch.B. Edin., Junior Surgeon, Royal Infirmary, Doncaster.

Hutchinson, J. A., M.D., M.S. Durh., to be Certifying Surgeon under the Factory and Workshop Acts for Northallerton.

Linell, E. A., M.D. Manch., Assistant Professor of Anatomy in Charge of Department of Neurology, University of Toronto.

McDonald, J. R., F.R.C.S. Edin., House Surgeon at the Durham County Hospital.

Morton, R., M.B., Ch.B. Edin., Resident Medical Officer at the Royal Mineral Water Hospital, Bath.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Radiographer.

All Saints Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, and 91, Finchley-road.—Res. H.S. £200.

Birmingham, Queen's Hospital.—Third P. for Out-patients. £50.

Bolton, County Borough of.—Asst. M.O.H., &c. £600.

Bradford, Municipal General Hospital, St. Luke's.—H.P. and H.S. Each £200.

Carnegie Dunfermline Trust, Abbot-street, Dunfermline.—Asst. M.O. £550.

Cheshire Joint Sanatorium, near Market Drayton.—Dental Surgeon.

City of London Maternity Hospital, City-road, E.C.—Res. M.O. £100.

Dreadnought Hospital, Greenwich.—H.S. and H.P. Each £150.

East African Medical Service.—M.O. £600.

Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. £150.

Glasgow District Mental Hospital, Gartloch.—Jun. Asst. M.O. £350.

Halifax Royal Infirmary.—Third H.S. £150.

Leeds Education Committee.—Asst. School M.O. £500.

London County Mental Hospital Service.—Seventh Asst. M.O. £432.

Manchester Children's Hospital, Pendlebury, near Manchester.—Res. M.O. £120. Also Res. S.O. £80.

Manchester Children's Hospital, Gartside-street.—M.O. and Asst. M.O. £200 and £150 respectively.
Manchester City.—M.O. £632 7s. 8d.
Metropolitan Borough of Woolwich.—Asst. M.O. £400.
Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. £250.
Richmond Royal Hospital, Surrey.—Hon. S. to Out-patients.
Royal Naval Medical Service.—Surgeon-Lieutenants.
Royal Northern Hospital, Holloway, N.—H.S. £100. M.O. £150.
St. Mark's Hospital for Cancer and Fistula, City-road, E.C.—H.S. £200.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—H.S. £75.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. £100.
Sligo County Board of Health.—County Surgeon. £500. P. £250. H.S. £150.
Sunderland Royal Infirmary.—H.P. £160.
West African Medical Service.—M.O. £660.
West Bromwich and District Hospital.—Res. Asst. H.S. £180.
West London Hospital, Hammersmith-road, W.—H.P.; also two H.S.'s. £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Cerrig-y-Druidion, Denbigh; Polesworth, Warwick; Staveley, Derby; Bridgwater, Somerset; Harrold, Bedford.

The Secretary of State for the Home Department gives notice of vacancies under the Workmen's Compensation Act, 1906, for County Court Circuit No. 1, and for County Court Circuit No. 57. Applications for the former post should reach the Private Secretary, Home Office, not later than Sept. 8th, and for the latter not later than Sept 19th.

Births, Marriages, and Deaths.

BIRTHS.

CROOK.—On August 17th, at Chiswick-place, Eastbourne, the wife of Dr. A. H. Crook, of a daughter.

MCCALL.—On August 21st, at West Lodge, Leominster, the wife of H. Dundas McCall, M.R.C.S., L.R.C.P., of a daughter.

MURPHY.—On August 12th, at Middlewich, the wife of James Murphy, F.R.C.S. Edin., of a daughter.

WARD.—On August 21st, at Oaklands, Hythe, Southampton, the wife of Dr. G. Humphry Ward, of a son.

MARRIAGES.

DOUGLAS—NEWNHAM DAVIS.—On August 23rd, at St. Mary's Church, Silchester, Arthur McDonald Douglas, M.B., Ch.B. Glasg., to Kathleen, only child of Mr. and the late Mrs. H. Newnham Davis, The Grange, Silchester, Hants.

INKSTER—COX.—At St. Alban's, Holborn, on August 27th, John Inkster, M.D., M.R.C.P., of Middlesbrough, to Olive Mary, daughter of B. H. Cox, Esq., of Toronto.

WHITTLE—FRICKER.—On August 20th, at the Parish Church, Harpenden, Claud Howard Whittle, M.R.C.S., L.R.C.P., M.B. Camb., to Phyllis Lena Fricker, eldest daughter of Guy Carey Fricker, O.B.E., of Harpenden.

DEATHS.

BOSWELL.—On August 22nd, suddenly, John Irvine Boswell, M.D. Lond., J.P., of Crawley Grange, Newport Pagnell, aged 65.

BROOKHOUSE.—On August 20th, at Ashby House, Tweedy-road, Bromley, Kent, Charles Turing Brookhouse, M.D., J.P., aged 76.

GILBERT.—On August 10th, at Highworth, Reigate-road, Reigate, Sydney Gilbert, L.R.C.P. & S., L.A.H., L.M.

LEE.—On August 15th, at Box, Wilts, Edwin Lee, M.R.C.S., M.D., J.P. (late of Dewsbury).

RANDLE.—On August 10th, at St. Ruan Minor, Cornwall, Dr. James Mayne Randle, aged 74.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

LANGHO EPILEPTIC COLONY.—The Manchester Union has issued its report on this institution for the year ended in March last. The accommodation provided is for 240 men and an equal number of women, with a hospital of 32 beds. During the year the average number of patients was 456. Since 1908–9, when the average number of fits per patient per annum was 114, a steady improvement has been obtained, the number being 29 in the year of the report. The treatment consists of regular diet, appropriate medical treatment when necessary, and open-air employment. The colonists who are physically fit have regular hours of work—the men work in the gardens and on the farm, or in such occupations as joinery, painting, shoemaking, or tailoring; the women in the kitchen, laundry, or at sewing. Ample recreation is provided; there is a weekly dance and kinematograph entertainment. The staff employed numbers 104 officers, including 55 attendants.

Notes, Comments, and Abstracts.

PUBLIC HEALTH IN BENGAL.

THE population of the province of Bengal at the census of 1921 (excluding the Chittagong Hill tracts) was found to be 46,522,293, an increase of 2·6 per cent. on that of the previous census. (The population of Great Britain was 42,857,144 in 1921.) In Burdwan Division there was a decrease of 4·9, and in Chittagong an increase of 11·9 per cent. The birth- and death-rates were 28·0 and 30·1 per 1000, as compared with 30·0 and 32·7 in the previous year, and 30·8 and 31·3 for the quinquennium (1916–20). This birth-rate of 28·0 was the lowest on record, except 27·5 in 1919, and was lower than in any other province in India except Assam and the N.-W. Frontier Province. On the other hand, only four other provinces, Madras, Burma, Bombay, and Assam, returned lower death-rates. From special investigations carried out during the past five years among a population of 15,000 persons in three selected circles of Murshidabad district, it was found that annual birth-rates varied between 24·1 and 62·90 (average 48·0); and annual death-rates between 30·2 and 88·4 (average 46·9). Dr. Charles Bentley, Director of Public Health for the province, who forwards this report,[1] considers that the normal birth-rate is probably about 46·7 (with a range from 37 to 51), and the normal death-rate about 40·0 (varying from 35 to 50 (or even more). He estimates that the actual birth and death ratios for the year were 38·3 and 40·8, "the probable ratio of omissions in the records being about 27 per cent." Verification of vital occurrences is a matter of considerable importance; in Khulna district it was found that there were 52 per cent. of omissions in the births, and 46 per cent. in the deaths, registered; in the towns it is said to be even worse, the Registration Act being "now largely a dead letter." It is useless therefore to attempt any comparison, or explanation in detail, of the variations that are indicated by the statistics, except those for the city of Calcutta.

Economic Conditions and the Birth-rate.

For the fourth year in succession the deaths have exceeded the births in this province, the excess being most marked in the three districts of Darjiling, Jessore, and Nadia, where the decrease in population has been in a ratio of 13·5, 11·7, and 10·5 per 1000 respectively; in Calcutta district (which, by reason of the disparity of the sexes, has always shown an excess of deaths over births) the birth ratio was 19·1, and that for death 33·5 per 1000. With regard to the general question of the relation between birth-rates and the economic (favourable or unfavourable) condition of the population, Dr. Bentley states that "this correlation, contrary to what is generally believed, is a negative and not a positive one. . . . This is a discovery of the very greatest importance. . . . Increased prices of food grains, while bearing heavily on certain classes of the community, tend in the presence of reasonably good harvests to benefit greatly a large proportion of the population." It would appear, however, that for all classes except the actual cultivators and distributors of the food materials concerned, increase of food prices (unless accompanied by a corresponding increase of income) will diminish their ability to obtain the necessary amount of food. "In view of the facts stated it is clear that in Bengal measures aimed at restricting the prices of agricultural production may be fraught with the very gravest consequences to the health of the population, whose prosperity is almost wholly dependent upon two factors—the general character of the harvest, and the monetary return obtained by the sale of the crops." This may be admitted for the agricultural inhabitants, who form the bulk of the population of the province; but for the three million town-dwellers (who would necessarily be affected), and as a general proposition (the very opposite to the principle of free trade), there is much to be said on the other side.

Deaths due to Cholera, Small-pox, and Other Diseases.

There was considerable increase in the cholera mortality, compared with the previous year (80,547 deaths against 54,199); but in spite of this the death ratio was 4 per cent. below the decennial mean; the ratios per 1000 are not stated, but the actual deaths recorded in the quinquennium, 1911–15, numbered 462,018 (giving an annual average of 92,403), and in the years 1916–20, 377,364 (annual average, 75,473). The disease is usually at its minimum from July to September in Bengal. "Preventive measures should be initiated early in September," and "always pressed with special vigour also in February." The districts most affected were Mymensingh (3·8 deaths per 1000), Bogra (3·5), 24-Parganas

---

[1] Annual Report of Director of Public Health, Bengal. Calcutta: Secretariat Book Depôt. 1923.

(3·3), and Pabna (3·2); Darjiling escaped altogether. Preventive work is being undertaken (disinfection of water-supplies, use of cholera vaccine, &c.). In Dinajpur district, "wherever the disinfection of wells was undertaken, cholera quickly subsided." Excluding Calcutta, 4607 deaths from cholera were reported in the towns of Bengal, compared with 3863 in 1920; this is said to be "an increase of 42·3 per cent." On the figures given the increase would be 19·1 per cent., but it is stated that "the cholera death-rate is an obvious under-estimate and ought probably to be increased by at least 50 per cent."

There was a great decrease in small-pox mortality, 8157 deaths compared with 36,190 and 37,010 in 1920 and 1919, the corresponding death-rates being 0·18, 0·79, and 0·81 per 1000. "The great decrease is due to the usual periodical decline in the prevalence of the disease following the severe epidemic of 1919–20; the disease tends to recur in epidemic intervals of from five to six years," and 80 per cent. of the mortality usually occurs in the first six months of the year. In only four districts was there an increase over the decennial average (Jalpaiguri, Murshidabad, Malda, and Jessore); the highest death ratio occurred in Murshidabad (0·62 per 1000); in Calcutta it was only 0·10, compared with 1·02, the decennial average. "For the first time on record the returns make some attempt to differentiate between the various febrile affections as causes of death, which have previously all been classed under the general heading 'Fevers.'" Of the total 1,070,368 "fever" deaths, 737,223 are shown as due to malaria; but it is said that probably the deaths due to this cause are only one-half of this figure. In Chittagong division less than one-fifth of the "fever" deaths are now ascribed to malaria. It is stated that probably in the whole province from 20,000 to 60,000 deaths were caused by enteric fever (0·4 to 1·3 per 1000), the deaths so registered only numbering 5693. Only 1537 deaths were ascribed to measles, but probably the number should have been from 10,000 to 25,000. From kala-azar only 1552 deaths are reported, but if the Calcutta death-rate (0·2 per 1000) be "accepted as a fair indication of the incidence of the disease in 1921, the kala-azar deaths throughout the province cannot have fallen far short of 10,000, as against 1552 actually reported." "Plague has almost ceased to figure as a cause of death in Bengal." There were only 66 fatal cases in 1920 and 59 in 1921, of which latter 37 occurred in Calcutta and 16 in Hooghly and Howrah districts. The disease "has now reached so nearly to the vanishing point, that it should not be a difficult matter to eliminate it entirely." The great increase in deaths from "respiratory diseases," which began in 1918, due to the influenza epidemic, continues: there were 11,675 deaths so returned in 1917, 20,901 in 1918, 22,609 in 1920, and 32,367 in 1921. The heading now includes influenza, pneumonia, phthisis, and "other respiratory diseases," and many deaths formerly returned under "fever" are now placed in their proper category. Under influenza 4751 deaths were returned (0·1 per 1000), while in Calcutta the ratio was 1·0 per 1000. Dr. Bentley considers this latter ratio to be a fair representation of the prevalence throughout the province, which on this basis would mean over 46,000 deaths. In Darjiling district, which was most affected, the death-rate from this cause in the rural circles was 2·5, and in the towns of Darjiling and Kurseong, 21·4 and 7·1 per 1000. Pneumonia has now been given a separate heading in the returns, it is one of the most serious causes of death; but "only a fraction of the pneumonia mortality is correctly reported," many deaths being included under "fevers"; 11,567 deaths were returned, of which 3183 occurred in Calcutta. For phthisis the provincial death-rate was 0·1, for towns 0·9, and for Calcutta 2·3 per 1000; but with the exception of Calcutta all the figures are under-estimates. "We must therefore be prepared to see an apparent increase of tuberculosis in the future." The same must be expected in regard to dysentery and diarrhœa, which from the Murshidabad observations give an aggregate of 5·1, while the deaths actually recorded under these headings (22,258) give a ratio of only 0·5 per 1000. There were fewer deaths from suicide in 1921 (3217 against 3509 in 1920); 1819 were among females and 1398 in males, the sex proportions of the population being 22½ and 24 million respectively. Suicide among females was 30 per cent. in excess over males. In Jessore district the excess was 100 per cent. The population is 1,722,219, of whom 828,627 are females.

Deaths from hydrophobia have increased very considerably: for the years 1918–21 they have numbered 119, 179, 289, and 379 respectively. This "is most disquieting." In the Presidency division there were 170 deaths against 96 in the year preceding. "The need of facilities for preventive treatment is apparent. . . . As urged in previous reports, the question of providing for treatment in Calcutta merits careful attention." We entirely disagree with this opinion: there can be no doubt whatever that *immediate action* is required. Whether Calcutta is the most suitable place for a Pasteur institute, or no, is a matter for consideration, and other localities are available; but there can be no doubt as to the necessity for action. The successful results obtainable by early treatment should be well known in every province in India (if anywhere), and the failure to supply such necessary medical aid is to the ordinary mind inexplicable. The increase of hydrophobia deaths, from 71 in 1917 to 379 in 1921, would (it might have been supposed) have attracted the attention of some responsible authority before now, as it demonstrates the urgency of the need, and accentuates the inexplicable backwardness of the province, as compared with other administrative areas in the country. As far back as 1919, the Sanitary Commissioner with Government of India, referring to the increase in deaths from rabies in Bengal and Bihar, expressed the opinion that "a Pasteur institute more conveniently for these two provinces than is Shillong, seems indicated."

Neglect of Municipal Powers.

It is much to be regretted that, "with few exceptions, the administration of the Registration of Births and Deaths Act was grossly neglected by the municipalities charged with this responsibility. Similar carelessness was displayed in the administration of the Vaccination Act." The municipal authorities in most cases fail to realise that by the use of the powers granted to them they can greatly improve the health conditions of the areas under their control without increasing their expenditure in any way. The expenditure on sanitary works by Government, public authorities, and private individuals amounted to Rs.1,409,883, as against Rs.2,142,539 in the previous year. As an example may be noted the results of the "Flood and Flush Scheme" at Jangipur, in the Murshidabad district: the total death-rate has fallen from 52·7 per 1000 in 1918 to 31·1 in 1921; the infant mortality from 192 to 161, and that from malaria from 13·7 to 5·5. There has been a corresponding reduction both in the spleen index and in the prevalence of anopheles mosquitoes. Anti-malarial coöperative societies are making steady progress under the guidance of Rai Dr. Gopal Chandra Chatterjee Bahadur; there are now 25 branches in existence. "This movement is one of the most promising signs of the interest that has been awakened in disease prevention in recent years, and merits every possible support." Anti-stegomyia work in the ports of Calcutta and Chittagong was carried out by Dr. Batra, and very marked reduction in mosquitoes was effected. "Towards the close of the year orders were received to shut down the work at the end of the financial year." Mr. G. B. Williams, M.I.C.E., chief engineer in the Public Health Department, gives instances of the urgent need for new schemes of water-supply and drainage, and trusts that "if the financial position of the province is restored, one of the first uses made of any balance of funds available to take up as early as possible the programme of urgent sanitary works which is so imperatively necessary for the health of the community." In this hope he will be joined by all sanitarians both in India and at home.

Sanitary Measures: Lunatic Asylums.

In the Report on the working of the Municipalities in Bengal[2] during 1920–21, Mr. S. W. Goode, Officiating Secretary to Government, states that "it is a good sign that for the past few years almost all municipalities have been taking measures to improve sanitation by filling up or clearing insanitary tanks and ditches and by removing jungle; and in several instances effective steps were taken to prevent the spread of cholera and small-pox. The administration of Burdwan Municipality showed much vigour and zeal in obtaining suitable water-supplies, &c., and "the foundations of further progress have been laid." In Dacca Division the municipalities have shared in the difficulties universally caused by high prices, but have carried on their services without loss of efficiency. In Darjiling also the Commissioners are said to be progressive, and anxious to improve the amenities of their town, which is fortunate in the public spirit and mutual coöperation of its municipal representatives, as well as (we may add) the unrivalled beauty and grandeur of its situation. In other cases there appears to be failure of the executive local authority to make full use of the powers they possess. The Commissioner of the Presidency Division observes that "though the main difficulty is want of money, the result for the money spent is, in default of proper supervision, not always the best. Without the growth of a strong public opinion supporting sanitary measures, and vigorous control, there can be no marked improvement under present conditions."

Major T. C. Boyd, I.M.S., officiating Chemical Examiner to Bengal Government, in his report[3] for 1921, states that 1251 medico-legal cases were investigated, as against 1506 in the previous year; the decrease was chiefly due to fewer cases of animal poisoning, 214 less than in 1920, probably the result of the Poison Act. There was also a slight ecrease in human poisoning cases, 694 compared with 708 1920 ; opium was the poison most commonly detected.

---

[2] Calcutta: Bengal Secretariat Book Depôt. 1922.

[3] Ibid.

In the Lunatic Asylums[3] in Bengal, which altogether now ave a total capacity of 1121, the total population in 1921 umbered 1210 (including observation cases), as compared ith 1261 in 1920, the daily average present being 957, mpared with 966. Of these 106 were discharged cured 1·07 per cent. of average strength). The cures were iefly cases of mania (55), melancholia (21), and insanity used by *Cannabis indica* (24). There was no epidemic lness, but the average number of sick increased from 116 130, and the hospital admissions from 612 to 861 ; fever used 222 admissions, mostly at Berhampore ; and there ere 162 cases of influenza (mostly of a mild type) at Dacca 0) and Berhampore (82). The mortality was 68·9 per 00 average strength, compared with 105·5 in 1920. Of e 66 deaths, 10 were from dysentery, eight from acute ania, and eight from pneumonia. There was not a single eath from accident or injury in any asylum. At Dacca ·73 per cent., and at Berhampore 61·37 per cent. of the ean population were employed daily in industrial work, hich resulted in a total profit of Rs. 14,124. Major-General . H. Deare, C.I.E., I.M.S., who presents this short report, to be congratulated on the satisfactory results obtained this especially difficult sphere of medical administration India.

Hospitals and Dispensaries in Bengal.[4]

There was some decrease in the number of hospital atients treated in Calcutta during 1921 (445,088 as compared ith 482,110 in 1920) owing chiefly to closure of the Mayo ospital for repairs. The largest attendance of patients as for eye diseases (38,810 against 41,307 in 1920) ; next these affections came malaria (37,176 as compared with ,584) ; influenza also showed a decrease from 10,494 to 00. There were only 80 small-pox patients, compared ith 1346 in 1920. Cholera was somewhat more prevalent 446 cases and 365 deaths, against 1335 cases and 295 eaths) ; also kala-azar (2367 cases, as compared with 1821). enereal diseases, on the other hand, showed a decrease 0,624, compared with 23,120). The surgical operations erformed numbered 44,056, a reduction on those in 1920 5,223), chiefly due to the closure of the Ripon Street ispensary. At the district hospitals and dispensaries in e province medical relief was afforded to 7,564,957 patients, compared with 7,311,782 in 1920. Nearly one-third of ese were suffering from malaria (2,350,367, as compared ith 2,270,000 in 1920). Cholera also showed an increase om 9293 cases in 1920 to 12,664 in 1921 ; kala-azar from 61 to 9198 ; and leprosy from 2290 to 3831 cases. The heme for a leper colony has been approved, and a site quired in Midnapore district. At the various hospitals d dispensaries in the province 131,629 surgical operations ere performed, a slight falling off from the record of the evious year (132,058). Major-General Deare, in concluding s report, states that medical relief is hampered in almost l district hospitals and dispensaries for want of funds ; rmission has been given in certain cases to levy a small e, the very poor being excepted.

VOYAGE D'ÉTUDES MÉDICALES.

The first part of the official report of the sixteenth oyage d'Études Médicales,[5] which took place from ugust 27th to Sept. 16th, 1922, is devoted to a description the journey and of the places visited. It is written by r. Maurice Gerst, the Secretary-General of the V.E.M., d is an admirable account, as the writer of the present te, who was fortunate enough to take part in this journey n testify. The second part contains a clear and succinct mmary of the lectures given at the various stations sited by Prof. Paul Carnot, the scientific director of the yage, and by Prof. F. Rathery, the Assistant Director. hese contain details about the situation of each resort, e means of access, the special features of the climate and e waters, together with the indications and contradications. Among the places visited were Bordeaux, rcachon, Dax, Salies-de-Béarn, Pau, Eaux-Chaudes, aux-Bonnes, Cauterets, Bagnères de Bigorre, Luchon, and ulouse. The book will serve as a pleasant memento to ose who took part in the sixteenth voyage, as well as a eful handbook of information in regard to the places sited. It is admirably printed and illustrated by numerous otographs and a map. It may be well to state that these voyages " are a yearly function, and that different parts of ance are visited. Places are reserved for a certain mber of foreign medical men, and British practitioners siring to familiarise themselves with French spas have us a good opportunity to do so.

CONVALESCENT CARE ON A LARGE SCALE:

THE WORK OF THE BURKE FOUNDATION, NEW YORK STATE.

The Winifred Masterson Burke Relief Foundation, White Plains, N.Y., U.S.A., was founded and endowed by the late John Masterson Burke in memory of his mother. The actual establishment of the Foundation was by his desire postponed until after his own death in 1909, and in 1911 the institutional site at White Plains was purchased by the Foundation trust and work begun upon the grounds and buildings. Standing in 60 acres of land, the institution at present comprises 11 buildings—cottages for men and women, administration and dining blocks, laundry, power house, garage and stable, and superintendent's house—with provision for future extension. The institution was opened in April, 1915, and now holds 300 beds, divided between men, women, and adolescents in various disease classifications. In 1917 the entire facilities of the Foundation were offered to, and accepted by, the Government for military use. In May, 1919, when the Government handed the institution back, it had housed 2000 sick and wounded naval officers, sailors, and marines of the United States and Allied Nations. The review[1] of the work carried out during the two years 1921–23 states that early in this period the post-war reorganisation was completed, and normal institutional work resumed.

Advisory Work and Research Fund.

The Foundation takes an increasing part in the national movement towards systematic treatment of convalescent and " substandard " health conditions, giving facilities for inspection and consultation to those interested in its own and similar work. In 1921 the Frank K. Sturgis Research Fund was established and endowed by the president of the Foundation for the advancement of knowledge of convalescent and preventive treatment. The Fund assists other organisations and publishes and distributes literature dealing with its specialty. The city admission house of the Foundation in New York has become a central information bureau of convalescent and allied welfare ; working with other organisations, the Foundation is thus bridging the gap that so frequently occurs between a patient's return from convalescence and his settling down to some suitable occupation.

Régime of the Foundation.

Full use is made of the grounds at White Plains ; the question of transportation of convalescents has been studied and the value of distant removal proved, both in order to relieve homes and hospitals near the great centres of population and in order to deal boldly with cases which would benefit by such removal. A 25-mile motor-bus ride from New York tests the patient's reserve and adaptability, enabling him to be rapidly assigned to suitable quarters. The following quotation from the report shows the average day of a " progressing " male guest, and is stated to apply fairly to women and girls also, except that the latter play games and walk less.

" Rise at 6.30, no bathing requirements ; walk or sit out ; breakfast 7.30, make bed and tidy room ; morning papers, smoke (no repressions), wash and repair own clothing, go to ' canteen,' library, or barber shop ; play games outdoors and in, walks or light gymnastics ; glass of milk at 10, prescribed occupation 10.30 to 11.30 ; rest, dinner at 12.30, ' rest-hour ' 1 to 2, flat on bed with no talk (longer for weaker ones) ; play in or watch outdoor sports and tournaments, go to village a mile away, or do a few hours of work on farm grounds or buildings if on pay-occupation ; supper at 5, rest, walk, or games, read or write letters, dance and entertainment in assembly, lights out and bed at 9."

All convalescents come before the medical officer at intervals of from one to two weeks, for discharge and other decisions. Emergency medical service is always ready. " Nearly all brought medicines are taken away, as well as crutches, canes, and appliances, at the earliest feasible time. ' Doctoring ' and doctor-thinking is discouraged and replaced rapidly by formative near-normal interests and activities. The narrow drug-list used and the year's small total quantity for 6000 persons incites frequent incredulity. Nearly all begin what would become a series of complaints, but are met by the advice : ' Lie down, have temperature taken, skip a meal.' They are soon seen pointing for the dining-room and in three or four days the fears and introspections are past. Hydro, electro, and like physical therapies are not given, mainly for anti-neurotic reasons and because something better is provided."

Women, it is noted, generally wish to remain too long, and men to leave before recuperation is completed. Emphasis is laid on the importance of judging each case individually, and of taking into account handicaps, chronicity, and conditions of home and employment. Men and women are encouraged to meet in an atmosphere of middle-class social activity. The advantages of giving even the badly crippled a period of change and rest are pointed out, among them being that of temporarily "resting those left at home by taking out a worn and wearing member" of the family.

---

[1] The Winifred Masterson Burke Relief Foundation. Fifth Report, 1921–1923.

Prevention and Specialties.

It is estimated that one-fourth of the adult working population of the United States is in a condition of health sufficiently below the normal to warrant recuperative rest. The Foundation records slow progress in its effort to procure a larger proportion of "preventive" patients, with whom, as a class, results are most satisfactory. With regard to the special conditions treated, 80 beds are set apart for cardiac cases. Mild borderline nervous and mental cases are also taken; over a hundred of these types have already been returned to ordinary life, with a high average of improvement. Cases of lung abscess, hyperthyroidism, chorea, empyema, gastric and intestinal ulcer, "pre-tuberculosis," &c., have been benefited.

Nursing and Surgical Services.

One nurse to four or five infants and small children and, under favourable conditions, one nurse to 50 adults is the ratio of service; this ratio, it is pointed out, has only been attained through a system of generous enlistment of "patient-aid," which is of great therapeutic value to the assisting patients themselves. The actual expert staff consists of a directress, an assistant, three graduate day charge nurses, one nurse in charge of surgical dressings, one nurse for night supervision, and "three 'practical' nurses as aides." The head nurses are allowed to treat and advise medically to a considerable extent, their principal effort being to overcome the frequent desire of convalescents for drugs and medicines. Surgical dressings are made as simply and infrequently as possible and wound-coverings are reduced to a minimum. Convalescents with persistent wounds, sinuses, &c., are sent home to be handicapped wage-earners under private or dispensary care.

Diet, Occupation, Recreation.

Practically all grades of patients from New York City are stated to be "comparatively high and expensive feeders, with an unusual variety of fixed food ideas." At White Plains special dieting is not favoured; a carefully considered standard dietary is given, which results in the correction of many digestive and physical faults. "Obtain the right attitude towards food and exercise and the rest of the normalising process is easy." All patients after a few days of rest are given one or two hours of work daily. The work is prescribed in detail by the physician and is graded from sewing, basket-work, &c., to active gardening and work in the grounds. Women do all the sewing for the institution. "Long stayers" are given "pay occupation"—a modest wage for three to six hours' work about the grounds—and often pass into the regular employment of the Foundation. Recreation includes all manner of indoor and outdoor games, music, dancing, organised walking, &c. The extensive athletic fields of the Foundation are open to the Westchester County High School leagues and other organisations. The value of witnessing good sportsmanlike play is emphasised.

Conclusions Drawn from the Work of the Foundation.

From the eight years of the Foundation's work, covering 10,000 patients, the following conclusions have been drawn by the authorities in charge:—

1. Right selection of patients, keeping to the convalescent and preventive classes, is of the first importance.
2. Individualised term of stay avoids the waste and injustice of a set period.
3. Importance of the play and work and "help each other" therapies.
4. Selected cases of heart disease should be admitted in moderate proportion to all convalescent homes, as well as to special heart institutions.
5. Different ages, classes, sexes, races (with a few exceptions)[2] are successfully treated together.
6. A home-like atmosphere is not desirable; a measure of frank institutionalism, "with its democracy and momentum," gives superior results.
7. These institutions are useful as testing places for the patient's physical and general abilities and fitness for productive life.
8. The seriously ill may be safely returned over long distances in modern motor-cars.
9. More convalescent provision is required for the milder borderline nervous and mental cases, for certain respiratory conditions, for orthopædic cases, and for preventive phas generally.
10. Extension of convalescent facilities throughout t United States is essential for a balanced advance in publ health work.

RIPENING AND ROTTING OF HARD FRUIT.

IN a recent publication of the Food Investigation Boa (Special Report No. 12. H.M. Stationery Office. 4*s.* 6*d* Mr. Franklin Kidd, D.Sc., and Mr. Cyril West, D.Sc., de with the common disease of apples and pears known "brown heart." This consists essentially in the death a subsequent browning of the internal fleshy tissue of the fru while the peripheral flesh generally remains sound. Slight affected apples seen in cross section show small patches on of brown tissue. The disease does not appear external except that to the expert the fruit has lost its characterist springiness on handling. The authors in a long series investigations have shown the relation of this function disease to the atmosphere in which the fruit is store Apples and pears which remain free from blemish wh stored in air, develop this tiresome defect in atmospher containing percentages of CO_2 above a certain danger limi Below this limit the fruit tolerates CO_2 and low O_2 pe centages without injury, and such conditions may be employ to obtain a beneficial retardation of ripening in storag The critical limit of CO_2 content is about 13·6 per cent.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—Will you allow us to make a very urgent appeal f the Factory Girls' Country Holiday Fund? Our funds a exhausted, but we have many girls and women anxious hoping for at least a week's rest at the seaside before t winter. The need for this little rest and change is probab more urgent than ever before. Trade depression has result in the girls being the main support of thousands of famili who but for their earnings would be on the verge of starv tion. The general standard of comfort in the average hon is lower than it has been for many years, and the health the community in the crowded and airless factory distric of London has deteriorated considerably. Nor has it be possible for the girls to contribute as much towards a holid as they have done in former years. Good food, rest, a fresh air for a short time will make it possible for many continue their work through the winter, who would otherwi break down under the strain and privation they have h to bear for so many months. The short holiday will gi them fresh hope and courage. Subscriptions and donatio will be thankfully received and acknowledged by t treasurer, Mrs. Rendel, or Miss Canney, 75, Lamb's Condui street, London, W.C. 1.

We are, Sir, yours faithfully,

A. F. LONDON.
ALBERTA SANDWICH.
LOUISE CREIGHTON.
MARY ST. HELIER.
FRANK LLOYD.
F. H. HERTZ,
Chief Rabbi.
ROBERT F. HORTON.

August 23rd, 1923.

MEDICAL ACCOUNT-KEEPING SIMPLIFIED.

To the Editor of THE LANCET.

SIR,—It is generally recognised that members of t profession are not enamoured of account-keeping. May suggest to them an easy method, which I have adopted f some time, and found both simple and time-saving; necessary arithmetic being reduced to the simple form, t compound form being entirely eliminated. By reason of t fact that fractions of sixpence are never used in medic accounts, it becomes an easy matter to decimalise by usi the shilling as unit, and treating the 6*d.* as half-shilling five-tenths. Thus, such amounts as 21*s.*, 10*s.* 6*d.*, 7*s.* 6*d.*, 5 3*s.* 6*d.*, and 2*s.* 6*d.*, become *s.*21·00, 10·50, 7·50, 5·00, 3·5 and 2·50. The ordinary cash columns can be used for t purpose, two only being necessary, the pound column for t integer in shillings, and the shilling column for the fractio All figures to the left of the first figure of the integer natural represent half-sovereigns. Coins of this denomination havi no name, I have adopted for personal convenience the o one of "royal," familiar in Tudor days for this denominatio Pounds not being in the decimal series do not show the selves, but can be seen at a glance if required by mental or otherwise halving the "royals." Thus: 125·50 equa £6 5*s.* 6*d.* This decimal method has the additional advanta of privacy, for no inquisitive stranger would understand t figures, should the cash-book by chance be left lying abou It may be noted that there is nothing in the Coinage or an other Act, to render illegal the keeping or even rendering an account in any denomination we may choose, provided is intelligible.

I am, Sir, yours faithfully,

Chelsea, August 24th, 1923. W. W. HARDWICKE, M.D.

---

[2] "Coloured" convalescent patients are not admitted at White Plains. A small branch home for these patients at Valhalla, N.Y., was opened in 1915 in connexion with the Burke Foundation, but had to be closed after the entry of the United States into the war. Since that time help has been given in the form of recuperation at home and in country houses.

An Address

ON

EXTRA-SENSORIAL CHANNELS OF KNOWLEDGE

AND THE EXPERIMENTAL METHOD.

Delivered before the International Congress of Physiologists at Edinburgh, July 24th, 1923,

By CHARLES RICHET, LL.D. Edin.,
PROFESSOR OF PHYSIOLOGY AT THE UNIVERSITY OF PARIS.

Mr. President, my dear Colleagues,—I am happy find myself again among you and to affirm once ore my ardent faith in the unity of scientific men all lands, as well as my love for physiology. But e must at the same time show a wider and more ble patriotism in cherishing science, our common other. Therefore, leaving politics on one side, I ill plunge at once into the subject which I venture bring before you.

Although it may appear that I am deserting the assical paths of physiology, this is not really the se. What is our classical physiology if not the arching for truth by way of experiment, of which y illustrious master, Claude Bernard, has established e guiding principles with such authority that it ould be almost criminal not to follow them. To ote his words, "When you enter the laboratory, ave your theories in the hall with your overcoat." But," added he, with a smile, "you will be able to sume them when you go out again." A favourite ying of Pasteur was that it is as necessary to sweep ay the theories which encumber research as it is sweep out the dust every morning from the boratory.
